Mr. CHAUNCY PUZEY related a case of Multiple Wound of the Small Intestine with Penetration of the Gravid Uterus by a Stab. The patient, aged twenty-eight, came to the Northern Hospital in October, 1895. A loop of bowel was protruding from a small abdominal wound half-way between the pubes and the umbilicus. There were two wounds in this piece of bowel, one completely dividing it and the other cutting it half through. These wounds were closed by continuous Czerny-Lembert sutures. On extending the abdominal wound downwards there was a gush of blood and clots, and a second loop of bowel came out; this had been transfixed by the weapon and presented three wounds—two of the bowel itself and an extensive one of the mesentery—which bled profusely. The arteries being secured, the intestine was clamped above and below the wounded portion with Lane's clamp and nine or ten inches of gut were removed. The divided ends were joined by a Murphy's button (No. 2) and the rent in the mesentery repaired. The intestines were replaced and the abdomen irrigated with hot boracic solution. Dark blood welled up from the pelvis, which was filled with black clot. The incision was enlarged and the clots scooped out with the hands. A wound in the uterus was discovered which admitted two fingers; the divided umbilical cord protruded. The cord was pulled out and cut away. The uterine wound was closed with one thick chromic gut suture. The abdomen was flushed, a large drain-tube inserted, and the wound closed. Four days later the patient miscarried. She ultimately recovered, but the button had not passed. It was now apparently lodged in the sigmoid flexure.—Dr. MACFIE CAMPBELL said that he had seen the patient four days after the operation. There were at this time uterine contractions and a very offensive vaginal discharge. The os was patulous and some placenta presented. This was cleared away, but no fœtus was ever found. He presumed that the fœtus must have escaped through the uterine wound into the abdominal cavity and have been lost in the clots.—Mr. PAUL said he did not share in Mr. Puzey's fear that harm might result from retention of the button. He had used the button in seven cases; four recovered, including an extensive pylorectomy, and three died. In only one case could the button be blamed in the least degree.—Mr. BANKS made some remarks and Mr. PUZEY replied.

Mr. THELWALL THOMAS read a paper on the Operative Treatment of Varicose Veins of the Lower Extremity. He advocated a method of ligature and division of the internal saphena vein just below the saphenous opening. In some cases where a large bunch of varices existed at the inner side of the knee he noticed that there was nearly always a deep communication which necessitated the excision of a small bunch. Other cases could be cured by cutting and tying the external saphena at the lower end of the popliteal space. He read notes of seventeen cases in all of which union by first intention took place. When the limb is carefully bandaged after the operation thrombosis does not occur. In two cases a large varix was present at the saphenous opening; the ligature and division were performed immediately below this. It was astonishing to see old ulcers of the leg heal so rapidly as they did after the operation and not recur even in cases when the ulceration had lasted for years. The paper was illustrated by lantern slides of the patients before and after the operation.—Mr. ROBERT JONES had performed Trendelenburg's operation fifteen times, in some instances excising both internal and external saphena veins. Where ulceration existed the operation materially helped the healing process. The general results of the operation were most favourable. He laid much stress on the after-treatment, more especially the employment of massage in cases where there was brawny swelling due to lymphatic obstruction.—Mr. RUSHTON PARKER and Mr. LARKIN took part in the discussion.—Mr. THOMAS replied.

WIGAN MEDICAL SOCIETY.

Some Recent Advances in Surgery.—Exhibition of Specimens.

AN ordinary meeting of this society was held on April 14th in the board-room of the Royal Albert Edward Infirmary, Mr. C. R. GRAHAM, President, being in the chair.

The PRESIDENT read an exhaustive address on Some Recent Advances in Surgery, reviewing the operations and treatment of middle-ear and intracranial disease, laminectomy in injuries to the spine, cholecystotomy, resection of the intestines, operations for appendicitis, &c., and concluded with some remarks on the new photography and Roentgen's rays. An interesting discussion then followed.

The following cases and specimens were shown :—

Dr. MILROY: Patient suffering from Elephantiasis of Both Legs. Specimens of (1) Encephaloid Cancer of the Gall-bladder and Spigelian Lobe of the Liver; and (2) Fracture of the Body of the Third Cervical Vertebra with Hæmorrhage into the Cord caused by Indirect Violence in a Young Man; death in twenty-four hours.

Mr. BERRY: (1) Ununited Fracture (transverse) Wired with an excellent result; (2) Compound Fracture of the Elbow-joint; and (3) Triple Osteotomy (both femora and one tibia) in a child aged three years.

Mr. COWAN: Compound Depressed Fracture of the Skull in which he had trephined in three places. The patient was nearly well.

Mr. HUGH E. JONES: (1) Coloboma Iridis; (2) Choroiditis Senilis; and (3) Ophthalmic Demonstration of several cases.

Mr. MACDONALD: (1) Hydatid of Liver; and (2) Uric Acid Calculus from a Boy aged two years which weighed 134 grains.

Mr. WM. MITCHELL ROOCROFT: Mulberry Calculus removed from a Boy aged ten years which weighed 220 grains.

The PRESIDENT: Fifty-two Biliary Calculi removed by Cholecystotomy.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on April 14th, Dr ADOLPH BRONNER, President, being in the chair.

Dr. S. LODGE gave a demonstration of Micro-specimens illustrating Pathological Conditions of the Nose, Throat, Mouth, and Orbit.—Dr. GOYDER and Dr. HIME discussed the specimens.

Dr. H. BRONNER showed a patient who had recently suffered from Tetanus and whom he had treated with injections of antitoxin. Recovery was complete. The patient was a woman who was admitted into the Bradford Infirmary suffering from trismus. There were no stiffness of the muscles of the neck and no dysphagia. The knee-jerks were present. The pulse was 92, the respiration 24, and the temperature 100° F. Fifteen grains of antitoxin were injected and 20 grains of chloral hydrate and of bromide of potassium were given by the mouth. The patient had a spasmodic attack twenty-four hours after admission. At intervals 40 grains (followed by doses of 20 grains and 15 grains) of antitoxin were injected and there were further spasms of the neck and jaw noted. On the tenth day (after admission) pain in the back and legs was complained of; around the left knee-joint there was a roseolar rash, and the left wrist and shoulder were swollen and tender. There was a sore throat and the temperature was 104°. The after progress of the case was one of gradual improvement. Two abscesses in the back required to be incised and drained. The mode of action and the method of administration of the antitoxin were described.—The case was discussed by Dr. GOYDER, Dr. FARRAR, Mr. GABRIEL, Mr. HORROCKS, Dr. HIME, and Dr. CAMPBELL, and Dr. H. BRONNER replied.

Dr. J. HAMILTON CRAWFORD showed a man suffering from Idiopathic Muscular Atrophy.

Dr. FARRAR showed a Skiagraph of the Hand which disclosed a piece of Steel near the second Phalanx of the Little Finger, and described the apparatus necessary for the new photography.—Mr. PARKINSON, Dr. CAMPBELL, and Dr. GOYDER spoke on the subject and Dr. FARRAR replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on April 17th, Dr. NEWMAN being in the chair.

Dr. R. M. BUCHANAN showed specimens from a case of Cancer of the Pylorus. The special feature of the case was provided by the secondary distribution of the malignant elements. This had occurred widely in the lymphatic glands in various parts of the body and some of the glands were observed to have undergone caseous changes—an unusual circumstance in malignant growths. The peritoneum, pericardium, and right pleura were dotted over with a large number of minute secondary malignant formations, though no symptoms during life had suggested the involvement of these serous membranes.

Dr. WALKER DOWNIE related eight consecutive cases in which he had opened the larynx (crico-thyrotomy) for the purpose of removing Intra-laryngeal Tumours and showed several of the patients. The series included only one death, that of an adult who was the subject of a chronic lung affection and who died from septic pneumonia. The most noteworthy of the other cases were:—1. An adult from whom the left vocal cord was excised three and a half years ago on account of malignant disease and who had now a somewhat rough but distinct voice; in phonating the right cord would be seen to cross the middle line and rise up to meet the left ventricular band, which acted, therefore, as a substitute for the vocal cord. The disease had not recurred. 2. A boy aged five years on whom it was necessary to perform Tracheotomy for Attacks of Dyspnœa, one of which reduced the patient to a state of coma. The laryngoscope failed to detect any new growths, but on performance of crico-thyrotomy a small mucous polypus was seen to spring by a long pedicle from the tracheal wall about the level of the second ring, and the length of the pedicle was such as to allow the tumour to irritate the laryngeal mucous membrane and so lead to spasm of the glottis. The removal of the polypus was followed by complete cessation of the symptoms. 3. A child two years of age on whom Crico-thyrotomy had been performed six times for recurring papillomata. Dr. Downie expressed his conviction that growths within the larynx are much more satisfactorily dealt with by crico-thyrotomy than by an endo-laryngeal operation. He regards the operation as an eminently safe one and has had no trouble with subsequent malposition of the cartilages leading to aphonia. In order to secure accurate readjustment he is in the habit of making the incision in the thyroid cartilage, not in the middle line in its whole length, but commencing obliquely in one ala he reaches the middle line, continues downwards, and then completes the division obliquely in the other ala. Then when the divided parts are replaced they dovetail into one another and so accuracy of apposition is secured. For malignant growths Dr. Downie considers an endo-laryngeal operation quite unsuitable. Such growths are almost invariably larger and more widely extended than appears in examination by the laryngoscope, and they cannot be properly attacked unless by an operation which renders complete access to them possible. The patient who had now been free from any sign of recurrence for three and a half years after extirpation of the vocal cord for epithelioma illustrated the advantage of operating thoroughly and in an early stage of the disease.—Dr. NEWMAN agreed generally with Dr. Downie's views with regard to the crico-thyrotomy as compared with an endo-laryngeal operation. He quoted a case in which he had extirpated both vocal cords for malignant disease six years ago and in which there had been no recurrence. His experience had led him to the conviction that early operation in malignant disease offered a very good chance of complete cure, whilst when the disease had advanced to such a point that complete extirpation of the larynx was necessary it was almost as well to refuse to operate; one of his cases, however, had survived the operation for eighteen months.

Dr. J. H. TEACHER showed two patients illustrating the value of Skin Grafting in Promoting the Healing of Extensive

Digitized by Google

Wounds. In one the wound had been caused by the excision of a large part of the skin of the thigh on account of numerous small sarcomatous growths and the other was due to an accident. In each case it had been found that whilst epithelial grafts give rapidly a covering layer to the granulations this covering is thin and nothing like so permanently valuable as that provided by whole-skin grafts. Photographs representing the various stages of the healing process were exhibited.

Dr. NEWMAN showed specimens from a case of Malignant Disease of the Œsophagus which had terminated fatally in consequence of the ulcerative process extending into the aorta. The stricture had been recognised during life, the growth not only producing dysphagia, but also paralysis of the left vocal cord. Gastrostomy was successfully performed and for fourteen days progress was quite satisfactory. Then blood began to pass from the opening in the stomach and in the end death occurred suddenly from a severe hæmorrhage. The opening into the aorta was situated in the descending arch.—Dr. HAWTHORNE, in discussing the case, referred to the rarity of the mode of death in malignant disease of the œsophagus, and directed attention to a very similar case under the care of Dr. Frederick Taylor, reported in THE LANCET of April 11th 1896, p. 991.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

The Radical Cure of Inguinal Hernia.—Restoration of the Nose.

A MEETING of this section was held on March 20th, Sir W. THORNLEY STOKER, President, being in the chair.

Mr. HEUSTON read a paper on the Radical Cure of Inguinal Hernia, in the course of which he said that as hernia gave rise to a general weakening of the fascia transversalis in the inguinal region it was necessary in any operation aiming at radical cure to support and strengthen this fascia, and the most frequent cause of recurrence after some of the recent operations was neglect of this point. He then mentioned some of the operations now generally recommended, dividing them into those where the inguinal canal is not opened and those where the inguinal canal is opened; the results of the second variety were very good as it was possible to see which structure required most attention, but he feared that after a time recurrence would be likely to occur through absorption of cicatricial tissue. He then described an operation which he had himself performed on thirty-two occasions, the patients varying in age between eighteen months and fifty-two years; all of the patients recovered, and, as far as he could ascertain, the hernia had not recurred in any. This operation consisted in exposing the inguinal canal, separating the sac from the cord to its full extent, twisting the neck of the sac and ligaturing it by a Staffordshire knot with strong gut at its exit from the external abdominal ring, then suturing the twisted neck of the sac to the posterior and superior walls of the canal in such a manner as to approximate those walls and cause the twisted sac to become united to the posterior wall and fascia transversalis, thus hindering a recurrence through any portion of the posterior wall of the inguinal canal. He uses catgut sutures throughout the operation, and depends on inflammatory adhesions to hinder recurrence.

Mr. ROBERT H. WOODS read a paper on a Modification of the Indian Operation for Restoration of the Nose. The patient, a female aged twenty-nine years, had had the cartilaginous nose destroyed by lupus. The forehead flap was cut according to Dieffenbach's pattern. The skin from the bridge of the nose was detached and reflected downwards so that the raw surface looked forwards and the skin backwards towards the nasal cavity, the raw surface of this triangle was adapted to that of the forehead flap, and so formed a portion of the skin lining the new nose. The lining was completed by the flaps inverted to form the alæ, so that the whole new nose was lined with skin, and the tendency to contraction which is always present where a surface is left to granulate and cicatrise was obviated. The forehead surface was not sutured but was covered by a flap of skin, transplanted from the arm as in Wolfe's method. This flap perfectly covered the deficiency; it was absolutely wanting in sensibility. There was no secretion from the nose.

Reviews and Notices of Books.

Dictionary of National Biography. Vol. XLVI. Pocock—Puckering. Edited by SIDNEY LEE. London: Smith, Elder, and Co. 1896. Price 15s.

THIS volume contains upwards of 450 articles, the most noteworthy of which are probably those on Alexander Pope and Joseph Priestley. Mr. Leslie Stephen, to whom we are indebted for the biography of Pope, says of him that "he had qualities which would have enabled him to give an adequate embodiment in verse of the spirit of any generation into which he had been born. He might have rivalled Chaucer in one century and Wordsworth in another." The poet was a remarkable example of the association of great mental endowments with bodily infirmity, being of weakly constitution, greatly deformed, and only about four and a half feet in stature. He was born in Lombard-street in the City of London in 1688, died in 1744, and was buried in Twickenham Church. The versatility of Priestley's genius is sufficiently attested by the fact that the writing of his biography has been divided between two authors—Mr. Hartog undertaking the scientific and the Rev. Alexander Gordon the theological and political survey of his work. His discovery of oxygen gas was made on Aug. 1st, 1774, and was first publicly announced in a letter to Sir John Pringle dated March 15th, 1775. Scheele made the same discovery independently, but did not publish his results until a later date. Priestley also was the first to prepare seven other gases—namely, hydrochloric acid gas, nitric oxide, nitrous oxide, ammonia gas, carbonic oxide, sulphur dioxide, and silicon tetrafluoride. He and Professor Rutherford of Edinburgh simultaneously and independently discovered nitrogen in 1772. Priestley was born in Yorkshire in 1733, went to America in 1794, and died in 1804 at Northumberland in Pennsylvania.

The medical biographies are about twenty-four in number. Sir Francis Prujean was born at Bury St. Edmunds in 1593 and graduated as M.D. at Cambridge University in 1625. He was elected a Fellow of the Royal College of Physicians of London in 1626, was censor for several years, registrar from 1641 to 1647, president from 1650 to 1654 and treasurer from 1655 to 1663. He was knighted in 1661 and died in 1666. Prujean-square, a small passage leading off the Old Bailey, is named after him. Richard Powell was born in 1767, and graduated as M.D. at Oxford University in 1795. He was elected a Fellow of the Royal College of Physicians of London in 1796, was censor for several years, Gulstonian Lecturer in 1799, Harveian Orator in 1808, and Lumleian Lecturer from 1811 to 1822. In his Gulstonian lectures he mentioned the fact, up to that time unrecorded in this country, that impaction of biliary calculi in the gall-bladder does not necessarily cause serious symptoms. Dr. Powell was physician to St. Bartholomew's Hospital from 1801 to 1824 and was the first to print the whole text of the ancient charter granted to the hospital in the year 1137. He died in 1834. Sir John Pringle was the youngest son of a Roxburghshire baronet and was born in 1707. He studied medicine at Leyden, where he graduated as M.D. in 1730, and after some years of practice in Edinburgh he received in 1742 a hospital appointment with the British forces in Flanders. In 1744 he was made physician-general to the forces there, and in 1745 was present with the Duke of Cumberland at the battle of Culloden in Scotland, subsequently returning for two years to the army serving on the Continent. About 1748 he settled in London, still holding his appointment of physician to the forces, and rapidly attained professional distinction, being made physician to the Duke of Cumberland in 1749, to the Queen in 1761, and to the King in 1774. In 1763 he was elected a

Digitized by Google

Fellow of the Royal College of Physicians of London, in 1766 he was created a baronet, and in 1772 he became President of the Royal Society. He died in London in 1782. Pringle's writings and practical work did much for the advancement of military hygiene; his biographer (Dr. J. F. Payne) says that "he may fairly be regarded as the founder of modern military medicine in distinction from surgery." Percivall Pott was born in Threadneedle-street in 1714, and was admitted into the freedom of the Barber-Surgeons' Company in 1736. The union of the Surgeons and Barbers came to an end in 1745, and in 1753 Pott and John Hunter were elected the first Lecturers on Anatomy to the newly-formed Corporation of Surgeons. He became Assistant Surgeon to St. Bartholomew's Hospital in 1744, and was full Surgeon from 1749 to 1787, during which long period of active service he made many improvements in practical surgery. He was also the author of many celebrated treatises, the chief of which are those on Ruptures, on Fistula in Ano, on Injuries of the Head, on Fractures and Dislocations, on Curvature of the Spine with Palsy of the Lower Limbs, and his "Chirurgical Observations." The term "Pott's fracture" originated in his having himself sustained that injury in 1756 through being thrown from his horse. His practice was very large and the lectures delivered by him to the students of St. Bartholomew's Hospital were the most celebrated in London. He died in 1788. Sir George Hornidge Porter was born in Dublin in 1822, being the only son of Mr. William Porter, a distinguished Dublin surgeon, who was Professor of Surgery in the Irish College of Surgeons School of Medicine and filled the office of President of the College in 1838. Having studied medicine in his native city and become a Fellow of the Royal College of Surgeons in Ireland in 1844, he graduated as M.B. at Trinity College, Dublin, in 1845 and in 1849 was elected surgeon to the Meath Hospital, in the duties of which appointment he continued to be actively engaged for the remainder of his life. In 1865 he received the degree of M.D. from Trinity College, Dublin; in 1868 he was elected President of the Royal College of Surgeons in Ireland; in 1869 he was appointed surgeon-in-ordinary to the Queen in Ireland; in 1883 he was knighted, and in 1889 he received a baronetcy in recognition of his distinguished position as a surgeon. His literary work consists of numerous records of surgical cases and operations published in the periodical press. He died in 1895. Sir James Prior was born at Lisburn about 1790, entered the Navy in 1810, and became surgeon to three of the Royal yachts in 1815. In 1843 he was created deputy-inspector of hospitals, received knighthood in 1858, and died at Brighton in 1869. He had a considerable literary reputation, having published a memoir of Edmund Burke, which appeared in 1824 and passed through several editions, as well as some poetical pieces, a life of Oliver Goldsmith, and an edition of Goldsmith's miscellaneous works. John Postgate was born in Scarborough in 1820, took the diploma of the Royal College of Surgeons of England in 1844, settled in practice in Birmingham in 1851, became a Fellow of the College of Surgeons in 1857, and acquired a well-deserved prominence by his labours for the exposure and repression of the adulteration of food. Under his influence nine Bills were introduced into the House of Commons by the members for Birmingham. Postgate obtained no public recognition of any kind for his services. He was appointed professor of medical jurisprudence in Queen's College, Birmingham, in 1860, and died in 1881.

Sewerage and Sewage Disposal. By HENRY ROBINSON, M. Inst. C.E. London: E. and F. N. Spon. 1896.

PROFESSOR ROBINSON'S book deals with a most important subject upon which he is an accepted authority. It is disappointing, however, not to find in it any indication of a promise of the solution of the problem of really utilising sewage. It is, of course, an important thing to be able to purify sewage or to dispose of it in a sanitary way, but it would be far more satisfactory if it could be turned to useful account rather than be left with the chance of polluting watercourses, or in the form of sewage cake to go begging for want of a purchaser or given of an individual to take it away gratis in any quantity he pleases. Chemical treatment and precipitation have accomplished a good deal in effecting the purification of our rivers and in having a marked favourable influence on the public health, for which we are thankful, but the process in its entirety is not scientific. Mainly through the admirable researches of the Massachusetts Board of Health, and of the experiments of Mr. Scott Moncrieff, we are beginning to suspect that with a due study of the conditions we shall be enabled soon to "engineer" organisms so as not only to dispose of sewage but to convert it into an innocuous and a highly valuable agricultural product. Nature knows no waste, and we have only to patiently wrest her mystic plans of action from her to effect the same end. Professor Robinson's book is admittedly a summary of important data connected with water-supply, sewerage, and sewage disposal, and it places in the hands of the engineer many valuable facts that he should be in possession of. The first chapter relates to house drainage and is followed by memoranda relating to sewage, and then by a section on sewage generally, and the question of the formula of flow, &c. The chapter on river pollution is excellent, as is also the section on precipitation dealing with the more important methods in use. Included under this heading are the electrical method of Webster, which depends largely upon the formation of iron salt by electrolysis acting upon and precipitating the sewage matters, and the Hermite process. We find no reference to THE LANCET report[1] upon the latter process, which we believe was more exhaustive than any other report, giving as it did full details bearing on its chemical and bacteriological aspect. Filtration, in which the claims of the Scott Moncrieff method are epitomised, but not to any extent criticised, is then dealt with. The volume concludes with a diagram giving at a glance the discharges and velocities of oval and circular sewers.

LIBRARY TABLE.

Elementary Inorganic Chemistry. By A. HUMBOLDT SEXTON, F.I.C., F.C.S. Fourth Edition, revised and considerably enlarged. London: Blackie and Son. 1895. Price 2*s.* 6*d.* — Though we deprecate the publication of books written almost exclusively for purposes of examination we are pleased to find that the small work before us has arrived at the stage of a fourth edition. Despite the fact that it is adapted to the wants of students preparing for the Science and Art examination and the London Matriculation, it is a sound exposition of the facts and the general principles of chemical science. It is an excellent chemical primer, due and equal emphasis being given to theory and practice and a proper importance to the physical aspect of the changes in matter. The treatment of the subject is scientific although simple, and it is this feature which singles out this elementary work from a shoal of others which have no real *raison d'être.*

Hygiene. By Professor J. LANE NOTTER, M.D. Dub., and Surgeon-Major R. H. FIRTH, F.R.C.S. Eng. Second Edition. Longmans, Green, and Co. 1895.—The rapid exhaustion of the first edition of this work has necessitated the issue of a second edition within only a few months of publication.

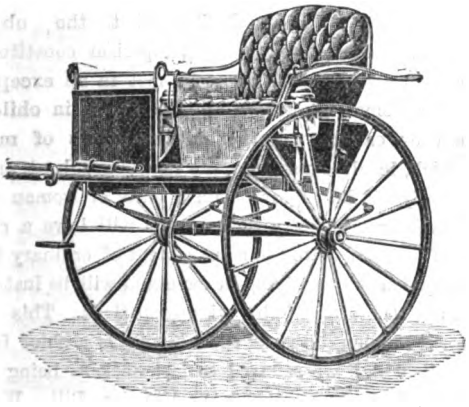
Expansion and growth are the natural conditions of manuals when re-issued, but we are glad to see that the authors have not added much to the bulk of their new volume. The new material which has been added is chiefly to be found in the chapter on the "Removal and Disposal of Refuse and Excreta," which has been almost re-written and much improved on, and in the entirely new chapter on "Sanitary Law." This new chapter we welcome as a great addition to the work; in it is clearly set forth all that should be known or might be required by the head of a household; in place of analysing each Sanitary Act separately the general effect of legislation as a whole upon certain matters of sanitary importance is considered, the summary being limited to the law as applicable to England and Wales.

New Inventions.

VEHICLES FOR THE USE OF MEDICAL PRACTITIONERS.

CARRIAGE-BUILDING has of recent years undergone several improvements, and some novel features have been introduced, designed chiefly either to reduce the weight of the vehicles or to render them more comfortable and commodious in use. These various desiderata appear to have been carefully and successfully studied by the Cortland Wagon Company of Henrietta-street, Covent-garden, and it may be useful to direct attention to a few styles of vehicle which seem to possess qualities likely to be serviceable to medical men. The Henrietta Gig or Car (Fig. 1)

FIG. 1.



weighs about 2¼ cwt., and is suitable for a horse standing from 14 hands to 15½ hands. It has elliptic springs, hickory wheels 4 ft. high provided with steel tyres, and from its lightness and strength is well adapted for long journeys over unfavourable roads. It is well finished and cushioned, and carries either one or two persons.

The Bombay Cart is slightly heavier than the foregoing. It carries two in front, and if required can be fitted with a Syce's seat in the rear suitable for use in India, as well as with a pole when a pair of horses are to be driven.

To those who desire increased protection in winter weather, or against wind, sun, and rain, the four-wheeled hooded carriages (Fig. 2) offer many advantages. They are seated for two persons, may be drawn by either one horse or a pair, and have ample space for instrument bags and similar requisites. The hoods fold up and can be opened or closed at will; the spaces at the back and side are filled by leather curtains.

The Cortland Stanhope Phaeton is a somewhat larger style of four-wheeled carriage, carrying two in front and two behind. This phaeton may be driven with either one horse or a pair, in which latter case a pole is supplied. It is very light in draught and turns in a small space.

The Cortland Bellamy Trap is a four-wheeled carriage constructed to carry a party of four, but the back seat may

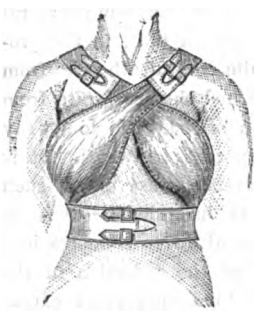
FIG. 2.

be folded up when not in use. Either one horse or a pair may be driven in it.

In all these vehicles the excellence of the materials is guaranteed, and the execution of needful repairs is facilitated by interchangeable parts being kept in stock. When required any carriage can be fitted with indiarubber tyres, either solid, as commonly used for hansom cabs, or pneumatic. American harness is supplied to purchasers who prefer it; it differs in some respects from the English patterns, the bearing reins in particular being less irksome to the horses.

THE "ELLISON" BREAST BANDAGE.

WE have received from Messrs. W. H. Bailey and Son, 38, Oxford-street, W., a little appliance which we can conceive might be of considerable practical use in many circumstances. It is a form of breast bandage consisting of a waistband of strong linen and braces of the same material made to cross at the back just above the lumbar region and in front at about the junction of the superior and middle portions of the sternum. The accompanying illustration shows that the front of the braces are expanded on either side into shallow linen bags, which will receive the respective breast and support it in any direction and with any required amount of tightness, according as the straps upon the collar-bone are adjusted. Pressure can of course be regulated and applied in this or that direction by the insertion of pads within the bags. The bandage may also be used for securing dressings or poultices, when it will obviate unnecessary moving of the patient. It is made in three sizes, small, medium, and large, and the price is 5*s*. 6*d*.



A LITMUS PENCIL.

LITMUS is an admirable indicator of acids and alkalies, but for this purpose can only be relied upon when pure. Its preparation in a pure state is not easy and involves a series of operations which take an inconveniently long time. The litmus pencil provides us at once with the pure colouring material in a very convenient form for use. Thus by merely tracing a piece of paper with the pencil a mark is obtained which we find is extremely sensitive to minute quantities of acids and alkalies, according, of course, as to whether the blue or the red end of the pencil has been used. For the practitioner in testing, for example, the reaction of urine it will be invaluable because reliable, and the indication it gives is distinct. The specimen was sent to us by Messrs. T. Christy and Co. of 25, Lime-street, E.C.

THE LANCET.

LONDON: SATURDAY, APRIL 25, 1896.

THE question of midwifery attendance on women whose position in life is just above that of paupers is becoming more simple, and the parties that have been ranged on opposite sides of the controversy are now finding out—as some have seen all through—that the differences between them are not great. As the discussion has proceeded the objects to be aimed at and the dangers to be averted are more clearly seen. Both are very real, as we shall try to show, and both place the profession in a delicate and responsible position, in which the help of practitioners in every grade of practice is needed. We have said that the objects to be aimed at and the dangers to be averted are very real. The great object is the saving of hundreds or thousands of lives of parturient women lost yearly through the ignorance of midwives. Dr. W. FRASER in his scheme[1] says that from 1871 to 1893 no less than 98,856 mothers died in England and Wales, or 4493 per year, from puerperal fever and the accidents of childbirth. As Dr. FRASER says, such a fact as this occurring in the antiseptic period of history may well cause searchings of heart. At a meeting lately held in Sheffield this mortality was attributed more to accidents than to puerperal fever, and rather to the want of skilled assistance than to the poisoning of patients by careless and ignorant attendants. This is, however, very doubtful. The serious matter is that while deaths from puerperal accidents are becoming fewer, the death-rate from puerperal fever is rising. Dr. BOXALL has shown that, in the provinces of England at least, while the death-rate from accidents of childbirth has diminished the death-rate from puerperal fever has considerably increased. We do not say that all the blame rests with ignorant midwives. It is enough to know that their ignorance must entail such consequences. Dr. W. WILLIAMS has shown[2] that in Wales the death-rate from puerperal fever is increasing, and he says that the prevalence of the infection in the thickly peopled mining valleys is to a very great extent due to the general employment of ignorant midwives. It is computed that 450,000 women are delivered annually by midwives, most of these midwives being quite untrained. It requires no effort of the imagination to picture the disadvantage and the disaster that such a fact implies. It is ascertained that a little training of midwives, with the opportunity of easy reference to a medical practitioner, vastly reduces the mortality of those whom they attend. This point need not be urged. Though labour be a natural process it leaves the woman a ready prey to the attacks of the most deadly microbes. The object of all enlightened and humane people, medical or lay, must be to reduce to a minimum the risks of the 450,000 women who, as a matter of fact, are attended mostly by ignorant midwives.

How can this object be attained? The best way would be to secure for all women the attendance of fully qualified medical practitioners. There are reformers in this matter, such as Dr. RENTOUL, whose suggestion is attendance by medical practitioners—male or female—and they say that there are registered practitioners of medicine, who, after six or eight years spent in general education, five in medical study, and a series of severe examinations, will be content to take these hundreds of thousands of cases at a charge of 7*s.* 6*d.* for each case. We neither believe this nor desire it. We should despair of our profession if medical men had to do the drudgery of 7*s.* 6*d.* midwifery. But though we see no chance of medical men taking the midwifery of mere midwives into their direct care, we fully appreciate both the necessity and the practicability of placing the midwife in such a relation to the medical practitioner that he shall be available in every emergency. Every Midwives Bill supposes this. Dr. RENTOUL requires the midwifery nurses whom he is willing to register to act under the immediate supervision (does this mean in the presence?) of a medical practitioner. We think, with the Lancashire and Cheshire Branch of the British Medical Association, that such an arrangement is impracticable. It would be as exacting to the practitioner as if he had no midwifery nurse, and two fees would have to be paid by the patient. Another way out of the difficulty is to throw the cost of the midwifery of the classes we are considering on the Poor-rate and to give them the benefit of the attendance of the Poor-law medical officer. This course is open to the formidable objection that it pauperises the patients. Accordingly the great majority of persons who have considered this subject have come to the conclusion that the obstetric needs of the classes just above pauperism constitute an exceptional problem which must be met in an exceptional way. The women cannot be allowed to die in childbirth because they cannot pay the minimum fees of medical men—which, in all conscience, are small enough at present. Consequently all Bills provide for a class of women to act as midwives or midwifery nurses, who will have a certain amount of training as to the management of ordinary labour and the hygiene of the lying-in room and will be instructed as nurses in the risks of the lying-in periods. This insistance on the nursing duties of the midwife is a chief feature of the Bills which we referred to last week as being likely to compete in Parliament with the Midwives Bill. What is wanted is a class of women who will do *both* duties as at present. It is obvious that the lying-in woman is as much at the mercy of the nurse as of the midwife, who in the poor woman's case are one and the same person. Ignorant or dirty nurses will do all the mischief of ignorant or dirty midwives. It is no use to save women from one and not the other risk.

> "What boots it at one gate to make defence
> And at another to let in the foe?"

It is to the credit of the Lancashire and Cheshire Branch that it emphasises very specifically the nursing function of the midwife. It will be the duty of the suggested Midwives Board to lay down rules for the training of the midwife, for her examination, and for limiting her to normal cases.

We have not space to-day to go minutely into the rival merits of the different Bills and of the clauses which

[1] THE LANCET, Feb. 29th, 1896.
[2] THE LANCET, April 18th, 1896, p. 1067.

Digitized by Google

are meant to avert the risks of this legislation. The greatest risk which it behoves us to avert is that of doing anything to detach midwifery from the science and art of medicine. It is only since midwifery has come to be studied in this relation that it has achieved its great improvements in saving life alike from accidents and from infections. It is of no use to argue that the results of midwives' practice in lying-in hospitals and charities afford proof of the propriety of giving them sole charge of lying-in women. The argument is utterly fallacious. In this connexion they are the mere handmaids and nurses of medical practitioners. And the test of safe legislation is the degree in which it ensures that the women who are to be registered as midwives and midwifery nurses shall continue to occupy the same relative position. The important letter of Mr. HUMPHREYS, which we print in another place to-day, shows that on some essential points there is a difference between the General Medical Council and the Privy Council. It is satisfactory to know that the promoters of the Midwives Bill sympathise with the General Medical Council and disapprove the action of the Privy Council or of the House of Lords in not accepting the suggestions of the General Medical Council which has a great responsibility in this matter. Some teachers of midwifery would seem to add very much to the difficulty of procuring reasonable legislation on this subject by rash statements. Dr. W. C. GRIGG is reported by Dr. RENTOUL as saying to his pupil midwives: "I am sure you will agree with me in hoping the day is not far distant when all midwifery will again fall into the hands of women." We cannot help thinking that Dr. GRIGG has been misreported. Surely he does not wish for so retrograde and disastrous a change as seems to be implied in this remark.

FOR months to come the Dongola expedition and the forward movement in the Soudan will be of absorbing interest, and already the arguments for and against this latest departure in our Egyptian policy are being stated and restated with conspicuous ability on either side. It is not within our province to criticise or defend that policy, but as medical journalists concerned in the future even more than in the immediate present of a great health resort for the English-speaking world we have a view of our own which is not without its interest even for the diplomatist and the military man. There are, indeed, two causes in Egypt—a sanitary and social work on the one hand, and a political and imperial one on the other; and while the latter is receiving an attention which no patriotic or far-sighted Englishman will grudge, the former is for the time being lost sight of, if not wholly relegated to the background.

No one can have followed our Cairo correspondence for the last few years without vividly realising two facts—to wit, that Egypt, particularly the upper reaches of the Nile, is becoming steadily an important factor in the resources of medicine—an aid to treatment which the English consultant has more and more to consider in the interests of patients; and, secondly, that the sanitary conditions of the country are very far from keeping pace with the influx of the ailing or the weakly in quest of warmth and pure air. In Cairo itself—which in the winter months has been not inaptly described as "almost a suburb of London," so full is it of our compatriots—the death-rate is at least three times as high as in either the English or the Scottish capital. It is, in the words of a recent reporter on its sanitation, "absolutely destitute of any drainage or sewage system," and on certain days when the wind blows, there being little or no rain to cleanse the streets, "the analysis of the air would yield results which ought to terrify the Government into sanitation." The condition of the towns further up the Nile is even worse, their defect in wholesome potable water being a byword. This is one, though by no means the only, cause why their native children die in such appalling numbers—"two-thirds of them before they are five"!—and it is a cause which cannot but affect disastrously the health of even the well-fed, well-cared-for sojourner from the British Isles. True, efforts are being made to remedy this defect by boring, and just as at Biskra, in the Sahara, artesian wells now supply he English-speaking resident with water he can drink with safety, so in Egypt the adoption of similar measures has already begun and nothing but a sufficient money grant is required in this, as in other departments of public hygiene, to make the country habitable by the stranger and healthy for the native.

But it is at this point that the sanitary and social cause for which we have been pleading comes into conflict with the political and imperial. The forward movement in the Soudan threatens to assume proportions which will drain the country of its resources for years to come and may throw back public hygiene for a decade and more. Relying for her prosperity as she does on "the foreign import," as the health-seeking sojourner is somewhat cynically called, Egypt is in danger of losing this source of income and with it the means of promoting that sanitary reform which is year by year becoming more indispensable for her as a climatic resort. Three millions sterling is the estimated amount of what Great Britain alone contributes annually through her visiting population to the Egyptian Exchequer, and this contribution will continue so long as the country attracts the health-seeker, but not a day beyond. Once let it be found that infective disease, the Nemesis of backward sanitation, endangers the English resident or neutralises the benefits he looks for and the stream of pecuniary gain which is to Cairo and the Nile towns what the fertilising flood is to Lower Egypt itself will be deflected into other channels, and places like Biskra will thrive at Egypt's expense and rectify their sanitary frontier, and with it the monetary one, in a sense which will make the contemplated "rectification" at Dongola or Khartoum a costlier one than its promotors bargained for.

There are, in fact, two conquests as well as two causes to be provided for in Egypt. There is the political and imperial conquest, into which we have now entered and of which we are far from seeing the end, and there is the sanitary and social conquest, barely begun but giving promise of success—in danger, however, of being compromised, if not suspended altogether, by its more dominating counterpart. As we have said, we have no wish to attack or vindicate the "forward policy" now in course of being carried out. We leave that to our political contemporaries. But our duty as medical

Digitized by Google

journalists would not have been fulfilled if, amid the arguments for and against that policy, we had failed to put in a word for the sanitary and the social crusade on which we have started. *Sanitas sanitatum, omnia sanitas* was once a political watchword. It is worth while recalling it now when it is apt to be forgotten in one of the chief health resorts of the English-speaking world.

THE death of Dr. WILLIAM SHARP of Rugby, recorded in our columns last week, removes one of the last of the holders of a medical degree conferred by the Archbishop of CANTERBURY and registered under the Medical Act. Although the obtaining of a medical qualification in this unconventional way is altogether at variance with modern views as to expediency and the fitness of things, it is nevertheless a time-honoured usage almost contemporaneous in its inception with the Royal College of Physicians of London and fully sanctioned by Act of Parliament. It was the rejection of the POPE'S domination by King HENRY VIII. which led to the English Primates being invested with the power of conferring distinctions which we of the present day consider to be the exclusive prerogative of a university. The granting of degrees in divinity, law, and medicine appears to have been exercised by the Popes independently of the universities, and the abolition of the Papal authority in this country by King HENRY would, therefore, involve some inconvenience to such of his subjects as had expected to receive the coveted titles through the instrumentality of the Church. This disability was, however, easily removed by the Act 25 HENRY VIII., c. 21, which is entitled "An Act concerning the Exoneration of the King's Subjects from Exactions and Impositions heretofore paid to the See of Rome, and for having Licences and Dispensations within this Realm without suing further for the same." Section 2 provides that the Archbishop of CANTERBURY shall have power to grant "all manner such licences, dispensations, compositions, faculties, grants, receipts, delegacies, instruments, and all other writings for causes not being contrary or repugnant to the Holy Scriptures and laws of GOD, as heretofore hath been used and accustomed to be had and obtained by your Highness or any of your most noble progenitors, or any of your or their subjects at the See of Rome." Degrees are not specified in this transfer of authority, but they are understood to be included in the term "faculties." The right of conferring degrees was exercised by Archbishop CRANMER as early as 1539, in which year he commissioned the Bishop of NORWICH to confer the degree of Doctor of Divinity on ELIGIUS FERRERS. Only seven examples are known of Lambeth degrees granted prior to the Restoration—namely, one of D.D., four of B.D., one of M.A., and one of *ad eundem* B.A. After the Restoration in 1660 Archbishop JUXON (1660–63) bestowed degrees six times—D.D. twice, LL.B., M.A., M.D., and M.B. once each. His successors continued the practice, and the right of doing so—which was conferred, or presumed to be conferred, by Parliament under HENRY VIII.—was exercised by the Archbishops apparently without objection until in the reign of GEORGE I. it was disputed and made the subject of a law suit in consequence of the Bishop of CHESTER having refused to admit SAMUEL PEPLOE, a B.D. of Lambeth, to the wardenship of Manchester College. The cause was first tried at Lancaster Assizes in 1722 and was subsequently carried by appeal before the King's Bench, where it was decided in favour of the Archbishop in 1725. From the decease of Archbishop JUXON in 1663 to Feb. 1st, 1848, there were 451 Lambeth (or Cantuar.) graduates, namely:—D.D., 169; B.D., 11; LL.D., 24; LL.B., 41; M.A., 170; M.D., 31; M.B., 1; and Mus.Doc., 4. The solitary M.B. was PETER DENT, of Trinity College, Cambridge, who received the M.B. degree in 1678, and was incorporated at Cambridge in 1681. To the above list of graduates may be added the name of Mr. JOSEPH BRIGSTOCKE SHEPPARD, M.R.C.S. and L.S.A., of Canterbury, who was made LL.D. Cantuar. in 1885. This gentleman was seneschal of Canterbury Cathedral and was for many years distinguished as an archæologist; he died in January, 1895.

The Medical Act of 1858 recognised the Lambeth medical degrees to the extent that Section 15 and Schedule (A) provide for the registration of such degrees if granted prior to the passing of the Act, and the London and Provincial Medical Directory in the annual issues from 1848 to 1856 inclusive, but apparently not afterwards, at the end of the list of the "Institutions granting Degrees" had the paragraph:—"In addition to these the Archbishop of CANTERBURY is empowered to authorise any person whom he may deem fit to practise as a physician, by virtue of the Lambeth Diploma." The following is a complete list of the Lambeth Doctors of Medicine, together with the year of graduation, from the beginning of the present century to 1862. The other qualifications of each of these gentlemen, as far as they can be clearly ascertained, are placed within parentheses after the respective names:—In 1803, ROBERT POPE; in 1806, THOMAS DAY; in 1817, WHITLOCK NICOLL (M.R.C.S. Eng., 1809; L.R.C.P. Lond., 1816; M.D. Aberd., 1816; M.D. Glasg., 1826); in 1818, JOHN DAY; in 1819, CARR ELLISON LUCAS; in 1822, WILLIAM OLIVER LOCKE; in 1824, JAMES RUMSEY; in 1825, DANIEL JARVIS; in 1826, EDWARD GRIMSTONE; in 1827, Sir CHARLES MANSFIELD CLARKE, Bart. (M.R.C.S. Eng., 1802, F.R.C.P. Lond., 1836), and WILLIAM CHANDLER; in 1828, WILLIAM SAMWAYS OKE (L.R.C.P. Lond., 1828; M.R.C.S. Eng., 1838; L.S.A.); in 1836, Sir DAVID DAVIES, K.G.H. (L.R.C.P. Lond.); in 1840, ROBERT HULL (L.R.C.P. Lond., M.R.C.S. Eng., 1816); in 1841, Sir WILLIAM HYDE PEARSON; in 1849, JOSEPH LAURIE (L.R.C.S. Edin., 1837); in 1850, WILLIAM BAYES (M.R.C.S. Eng., 1844; L.R.C.P. Lond., 1853) and EDMUND CHARLES JOHNSON (M.R.C.S. Eng., 1843; F.R.C.S., 1858); in 1851, FREDERICK GILDER JULIUS (M.R.C.S. Eng., 1833; L.S.A., 1833; F.R.C.S., 1853) and JOHN GREEN BISHOP (M.R.C.S. Eng., 1809); in 1854, GEORGE CANNEY (M.R.C.S. Eng., 1841; L.S.A., 1843); in 1855, JOHN HODGSON RAMSBOTHAM (M.R.C.S. Eng., 1832; L.S.A., 1832; M.D. Erlangen, 1851) and RALPH BARNES GRINDROD (L.S.A., 1830; M.D. Erlangen, 1851); in 1856, WILLIAM SHARP (M.R.C.S. Eng., 1827; L.S.A., 1826) and EDWARD PHILLIPS (M.R.C.S. Eng., 1843); in 1858, EDWARD CRONIN (M.D. Dublin, 1828), EDMUND SMITH (M.R.C.S. Eng. and L.S.A.,

Digitized by Google

1827), and WILLIAM BAKER; in 1861, JOHN RAYNER (L.S.A., 1842; M.R.C.S. Eng., 1859; L.R.C.P. Edin., 1860; M.R.C.P. Edin., 1864) and EDWARD WESTALL; in 1862, WILLIAM SHERWIN.

The information as to the sources whence these particulars might be gleaned was supplied a considerable time ago by Mr. S. WAYLAND KERSHAW, M.A., the learned and courteous librarian at Lambeth Palace.

Annotations.

"Ne quid nimis."

ANNUAL REPORT (1894) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

WE have just received a copy of Mr. Shirley Murphy's third annual report as medical officer of health of the administrative county of London. The report for 1894 is a substantial folio volume running to about 170 closely printed pages and plentifully illustrated with charts, diagrams, &c. Relating as they do to the health and sanitary condition of the population of the English metropolis, which now numbers little short of four and a half millions, these reports have come to possess an importance not inferior to that attaching to the similar publications of the medical staff of the Local Government Board. The volume before us has been evidently prepared with the same care that had been shown in the compilation of its two predecessors. The subject matter is arranged in two main sections—the first statistical, the second administrative—and these are supplemented by a series of appendices, eleven in all, which give to the entire work a completeness that leaves nothing to be desired. In consequence, however, of the bulkiness of the volume, and the costliness of its illustrations, there is little hope that it will obtain adequate general circulation. Having regard to this consideration and to the great interest attaching to so important a work, at least to Londoners, we have resolved to deal with its several sections somewhat in detail, and to review the various points for the benefit of the readers of THE LANCET in our issues of the next few weeks.

THE USE OF CHLOROFORM IN DENTAL PRACTICE.

A DEATH under chloroform which has recently occurred during the performance of a dental operation serves as a sad comment enough upon the correspondence which has recently taken place in our columns[1] upon the subject of the justifiability of using chloroform during the extraction of teeth. The particulars of the case are as follows. The patient, a girl aged thirteen, suffered from neuralgia due to two carious teeth. Her health not being good the removal of the teeth was deferred and her general health attended to. However, a recurrence of pain occurred and her medical practitioner deemed it advisable to call in a local dentist and decided to give the child chloroform. At the inquest he was asked why he did not give the girl ether, and his reply is reported to have been that he thought that she would stand chloroform better. No reason for this assertion is given, nor is any mention made of any lung or renal condition being present which would have contra-indicated the employment of ether. The patient appears to have dreaded the pain, but was reassured when she was told that chloroform would spare her all discomfort. The anæsthetic was given from a mask "slowly and cautiously. Barely a drachm had been given when she was 'under.'" The dentist had some difficulty in getting out the first tooth. Although the patient did not feel anything at first she called out "oh" before the tooth was out and twisted herself round. At this moment "the pulse was good and she breathed deeply, the face became red." No more chloroform was given. The extraction of the second tooth was then attempted. The girl grew white in the face, the pulse imperceptible, and the breathing stopped. The usual restorative measures failed to restore animation. The chloroform used was from a good maker and had been safely used for another patient. The chloroformist stated that death was due to heart failure, and added "perhaps fright had something to do with it."—In addition to the above we note that the *Times* of the 22nd inst. contains the following:—"One of the district coroners of the West Riding, Major Taylor, has held an inquest at Idle on the body of Lavinia Sawdon, fourteen, who died while under the influence of chloroform on Friday afternoon last, administered by Joseph Priestley, 'herbalist and maker of artificial teeth.' The case has since been before the magistrates. Evidence as to the death of the girl was given. She called at the shop of Priestley to have two teeth drawn and she consented that chloroform should be used. She died in a chair after a second dose had been administered. Priestley had no assistance. Dr. R. Honeyburne spoke to the girl being perfectly healthy, and said a medical man would never, as a rule, both administer chloroform and extract teeth. The coroner at the inquest directed the jury to consider whether the act of Priestley was a grossly rash act or whether it was a case of misadventure. The jury deliberated an hour and brought in a verdict of 'Manslaughter' against Priestley. Before the West Riding magistrates he pleaded 'Not guilty' to the charge and reserved his defence. He was committed for trial at the next Leeds Assizes, bail being accepted."

[1] THE LANCET, March 21st and 28th, 1896.

THE FALCON-COURT IMPROVEMENT SCHEME.

THE London County Council, in pursuance of a scheme for the improvement of an insanitary district of Southwark, propose to sweep away no less than 111 houses in Falcon-court and adjoining courts and alleys. The evidence of Dr. F. J. Waldo, medical officer of health of the district, as given before the Local Government Board representative, bears out the fact that the destruction of these premises is an undoubted improvement. The Falcon-Court area, said Dr. Waldo, is hemmed in on the west by lofty model dwellings, on the east by houses lining the Borough High-street, and on the north and south by warehouses. In addition a manufactory, the Midland Railway Receiving Depôt, and other warehouses stand between the parallel courts and alleys comprised in the unhealthy area. This arrangement—an obstructive one—taken in conjunction with an existing faulty construction and grouping of houses in the area in question, effectually prevents a due admission of light and air. The dwellings themselves in many cases have no means of obtaining a through ventilation, and in those instances where a backyard is present such yard is usually narrow and insufficient for purposes of ventilation. The cellars, especially of the back-to-back houses in Falcon-court, often contain the waterclosets, ash-pails, and other sanitary conveniences. They also serve as kitchens and are generally used for the washing and drying of clothes as well as for other purposes. The occupied houses cover together one acre, thirty poles—that is to say, rather under one and a quarter acres—and upon that space 822 human beings are concentrated. The population density for the whole parish of St. George the Martyr is 211 to an acre, as against 58

Digitized by Google

for London. Eighty-nine deaths in this area are known to have occurred during the four years 1892-93-94-95, which figures give an average death-rate of 29·5 per 1000. The (corrected) death-rates for 1892-93-94-95 are 24·6 for the whole parish and 19·7 for London. During the three years 1893-94-95 188 official notices have been served under the Health Acts on owners and occupiers of property within the area under inquiry. This action, however, has only touched the fringe of a long-standing and insanitary evil, and has merely ended in the removal of a few of the grosser and more glaring defects. On the other hand, those faults of a structural nature, which are both many in number and of a serious nature, can only be mended by radical measures in the shape of a rehousing scheme followed by demolition of the buildings covering the area.

THE JENNER MEMORIAL FUND.

THE collection of "Jenner Relics" got together by Mr. Frederick Mockler of Wotton-under-Edge, and shown by him at the Bristol Exhibition of 1893, has been accepted by the Dean and Faculty of Medicine, University College, Bristol, to be located there, provided that the necessary amount (£1,000) to purchase it from the owner can be raised by public or other subscription. The Centenary of Dr. Jenner's decisive and successful experiment in vaccination will be May 14th, 1896, and now that the value of his work is receiving such terrible confirmation in Gloucester—the very town to which he belonged—we cannot but believe that the required sum will be forthcoming. Intending subscribers, of whom a very fair list has been already announced, will greatly oblige by sending in their names at their earliest convenience to the hon. treasurer, Mr. W. H. Greville Edwards, or to the secretary, Mr. D. Butler, 114, North-road, Bristol. Cheques should be made payable "The Jenner Memorial Fund" and crossed "Messrs. Prescott, Dimsdale, Cave, Tugwell, and Co., Limited, Bankers, Bristol." To each subscriber of one guinea and upwards a silver medal, and of half a guinea a bronze medal, commemorative of the Centenary of Dr. Jenner's successful experiment in vaccination will be presented at the close of the list.

THE TSETSE FLY DISEASE IN ZULULAND.

THE tsetse fly disease, called "nagana" by the natives, occurs in the horse, donkey, ox, and dog, and varies in duration from a few days or weeks to many months. It is uniformly fatal to the horse, donkey, and dog, but of the cattle affected with it a few recover. It is characterised by fever, more or less rapid destruction of the red blood corpuscles, extreme emaciation, and infiltration of coagulable lymph into the subcutaneous tissue of the neck, abdomen, or extremities, which consequently become swollen. Post-mortem examination shows the presence of a yellow, gelatinous material in the subcutaneous tissue and under the serous covering of the heart, ecchymoses in various regions, and congestion and fatty degeneration of many organs. Geographically it is limited to certain warm and moist tracts which in Zululand are situated in the vast plain extending from the coast inland for a distance of some fifty miles. The disease is not new; it has existed in such districts time out of mind. The tsetse fly (Glossina morsitans: Westwood) is about 11 mm. or seven-sixteenths of an inch in length, and has transparent wings about 10 mm. long. On the upper surface of the abdomen there is a longitudinal yellow line with four yellow lines crossing it at right angles. In 1894 Surgeon-Major David Bruce, A.M.S., discovered that the blood of animals suffering from the tsetse fly disease invariably contained a [illegible]ozoon which had not been previously observed in Africa, but which he considers to be either identical with or closely resembling the Trypanosoma Evansi found in surra, a disease occurring in India and Burmah; surra, however, as known in India, does not affect cattle. In fresh blood these hæmatozoa are seen as actively moving transparent elongated bodies, in thickness about a quarter of the diameter of a red corpuscle, and in length about two or three times the diameter of a corpuscle. One end is bluntly pointed and the other is prolonged into a very fine lash, which is in constant whiplike motion; the body is cylindrical and has a transparent, delicate longitudinal membrane or fin, which is also in constant motion. In September, 1895, Surgeon-Major Bruce, under instructions from the Governor of Natal, proceeded to Ubombo in Zululand for the purpose of continuing his investigations. He believes that the fly acts only as a carrier of these microbes from infected to susceptible animals and does not cause the disease by means of any poison elaborated by itself. A limited number of flies may bite a susceptible animal over and over again without producing any ill effect, but when a horse is taken into the fly country for even a few hours, or when numerous successive relays of flies freshly caught in the fly country and brought into a healthy district are made to settle on an animal there, the disease is almost inevitably set up. Five flies kept in a cage with muslin sides were allowed to bite the shaved abdomen of a small dog every two days from Sept. 25th to Nov. 28th, but the animal remained quite healthy. On the other hand, flies which had fed for a short time on a dog affected with fly disease were allowed to bite another dog on Nov. 21st, 23rd, 25th, and 29th, the effect being that on Dec. 5th hæmatozoa were found in its blood. In order to show that neither food nor water is the channel by which the disease is conveyed two healthy horses, provided with network nosebags, were taken into the fly country from about 10 A.M. to 4 P.M. on Sept. 19th, 24th, and 29th, but were not allowed to graze or drink. Many flies settled on them and they both contracted the disease, one on Oct. 4th and the other about Oct. 28th. Another experiment was made by bringing to Ubombo tsetse flies caught in the low country and allowing them to bite a healthy horse; 129 flies were used in this way on ten days from Nov. 22nd to Dec. 14th, the horse fell ill on Dec. 15th, and the hæmatozoa were found in its blood. The source from which the fly obtains the hæmatozoa still remains to be discovered. Copious details, with drawings both of the hæmatozoa and of the fly (those of the fly being coloured), are given in Surgeon-Major Bruce's report on the subject, presented to the Governor of Natal and printed by Messrs. Bennett and Davis of Durban. Our columns last year[1] contained a similarly interesting memoir on the horse sickness of South Africa by Dr. Alexander Edington.

THE OUTBREAK OF GLANDERS IN LIVERPOOL.

THE somewhat exaggerated reports of the spread of glanders in horses in Liverpool have not been unattended with good results, as they have had the effect of putting team owners and others on the alert. At the same time there is no doubt that an outbreak, which might have been attended with the most serious consequences, has, we are pleased to hear, been practically nipped in the bud. This is due to the prompt measures adopted by the Health Committee of the City Council, a deputation from which body, we understand, waited on the Board of Agriculture last week in order to obtain powers for the effective repression of the disease. We are informed that the Liverpool deputation laid before the Board the necessity for isolating horses which had been in contact with diseased animals, powers which, it appears, are not now possessed by

[1] THE LANCET, Aug. 24th, 1895, p. 477.

Digitized by Google

the Board of Agriculture, and for which a special Act of Parliament is required. The deputation also suggested the compulsory notification of disease amongst horses; they also alluded to the importation of horses from abroad, by means of which, it was stated, influenza had been imported into the city, especially by horses from American and Canadian ports. They strongly advocated a compulsory system of inspection and the isolation of all imported horses. It seems most anomalous that horses can be landed from abroad without inspection and sent about the country from stable to stable irrespectively of diseased conditions; legislation on this point is absolutely necessary, as the powers now possessed by local authorities are restricted to ordering the slaughter of horses found to be affected with glanders. As a result of the interview between the Liverpool deputation and the Board of Agriculture a scheme was agreed on, in the absence of Parliamentary powers, which is much the same as that adopted by the London County Council, viz.—to isolate horses in sheds somewhere in the suburbs under the supervision of the veterinary superintendent. The owner of a horse which is suspected of being infected with glanders can send the animal to the isolation shed, the mallein test, with his consent, will be performed, when, if the horse reacts to the inoculation, it will be placed in a separate shed and frequently treated with mallein. Should the horse recover the owner must pay for its maintenance and treatment; but if, on the other hand, it develops symptoms of glanders the animal is to be slaughtered, the owner receiving as compensation one-fourth of its original value. As an estimate of the disastrous results which would accrue to Liverpool by the spread of this disease, we may mention that it is computed that 12,000 horses, some of great value, are employed by team owners, whilst tramways, cabs, and omnibuses employ between 6000 and 7000 more.

THE PERSISTENCE OF EXCITABILITY IN DIVIDED NERVES.

THE duration of the excitability of the distal end of a divided nerve is a point that has attracted the attention of many observers, and Longet, more than half a century ago, stated as a fact which has been very generally accepted that after division of the facial, hypoglossal, and sciatic nerves in the dog the most remote branches of the distal portion ceased to respond to stimuli after the lapse of four days. The first part of the *Archives de Physiologie* for the present year contains a short communication from Professor Arloing, a practised and careful experimenter, in which some strictures are made upon Longet's statement and evidence is adduced showing that the irritability of the divided nerve is not always uniform in the date of its departure and that considerable variations may be observed both in different genera and even in different animals of the same species. Thus Ranvier observed that whilst irritability might persist in the dog for four days, it was lost in the rabbit, guinea-pig, and rat in the course of forty-eight hours, and after the lapse of sixty-two hours in the pigeon. Ranvier also pointed out that it disappeared more quickly in young animals than in adults and in vigorous animals than in those that were ailing. Professor Arloing himself found that in the horse, ass, and mule the persistence of irritability in the branches of the facial nerve after section of the trunk was remarkable, being prolonged in some cases to the thirteenth day. The particular instance in which the functional activity of the nerve lasted to the thirteenth day was in an ass in which the facial nerve had been divided. Different nerves seem to vary in their faculty of retaining their irritability, for whilst in one case the peripheric extremity of the divided facial nerve retained its excitability for five days, the corresponding portion of the divided median and of the moderator of the heart had both lost their excitability between the fourth and fifth day. A physiological and highly valuable test is thus afforded of the existence of certain doubtful nerves. Professor Arloing, for example, has in this way satisfied himself of the presence in the cervical portion of the vagus nerve of the ass, besides the cardiac inhibitory, cardiac accelerator fibres, and motor fibres for the larynx and œsophagus, of yet a fourth set which is characterised by the retention of its excitability for three weeks after section, and which he regards as the ordinary motor nerve of the myocardium.

THE ABUSE OF MATERNITY CHARITIES.

WHEN other charitable medical institutions are trying to administer charity without abuse it behoves the authorities of lying-in hospitals and maternity charities to do the same. There is some reason to believe that tickets for the midwife are granted loosely to those who can afford to pay the ordinary fees. This is contrary to public policy and to the understanding with the good charitable people who subscribe. We feel persuaded that the committees of such charities will not resent a reminder on this point. The midwife should not be the almoner of letters and evidence should be forthcoming in every case of the circumstances of the patient.

THE LATE DR. WILLIAM SHARP.

DR. WILLIAM SHARP of Rugby died at Llandudno on April 10th, aged ninety-one years. He was born at Armley, near Leeds, studied medicine at Guy's and St. Thomas's Hospitals, and became qualified as L.S.A. in 1826. Next year he took the diploma of the Royal College of Surgeons of England, studied in Paris for a time, and settled in Bradford in 1828. In 1840 he was elected a Fellow of the Royal Society in recognition of his advocacy of local museums. In 1843 he removed to Hull and in 1847 to Rugby. Dr. Sharp was a prolific writer, and in 1856 the degree of Doctor of Medicine was conferred on him by the Archbishop of Canterbury. This Lambeth (or Cantuar., which might, by the way, be mistaken for Cantab.) degree supplies an interesting chapter in medical history and is dealt with at length in another portion of our issue.

THE STUDY OF PHYSIOLOGY IN MOSCOW.

AT present, when the attention of the medical world is being drawn to Moscow, any information concerning the medical schools, laboratories, and institutions of that city is of interest. Some time ago the committee of organisation of the International Medical Congress issued a series of papers giving descriptions of some of these institutions. The first one that has come to hand ("Le Laboratoire de Physiologie de l'Université Impériale de Moscou," par M. le Dr. B. N. Popov) gives a short account of the Institute of Physiology of the University of Moscow. This institute was founded in 1862, when Professor Einbrodt was elected to the chair of Physiology, and has since that time gradually expanded first into two chairs—histology and physiology—and then into a double professorship, Professor Chérémétevesky nominating Professor Morokhovetz as professor agrégé. Professor Morokhovetz, as a result of careful planning and of visits to the various large Continental laboratories, has been able to found and equip a physiological institute, which appears to be exceedingly well arranged and to be supplied with all the requirements of a modern laboratory. A list of the papers, fifty-one in number, that have come from this department since the year 1857 is worth studying as indicating what has been done in a very quiet way during the last forty years. In a second pamphlet ("Appareils et Instruments à l'Usage des Physiologistes construites d'après les dessins de M. le

Digitized by Google

Professeur Léon Morokhovetz, Moscou") a list of the apparatus designed by the writer and used in this laboratory is given; it is freely illustrated with photographs and plates, and a number of pieces of most ingenious apparatus which should attract the attention of those who take an interest in physiology are described. We recommend those who intend to make the journey to Moscow next year to keep these laboratories in mind.

THE SWISS NATIONAL EXHIBITION AT GENEVA.

FROM May 1st till the middle of October a national exhibition will be held at Geneva, and the programme which has been sent us promises well. Mr. M. J. R. Dunstan, the Director of Technical Instruction to the Nottingham County Council, has been appointed the official delegate of the Council to the exhibition with the object of making a thorough investigation into Swiss agricultural methods as exemplified in the central feature of the exhibition—the model village. Among the novelties to be introduced to the public at the exhibition is an instrument for "the cure of dyspepsia." A box or case is placed round the body in the region of the stomach and liver, a handle is turned, and "liquid air is pumped in through the pores of the skin." We abstain from further description of an apparatus which as yet we have only seen described on paper.

THE CLINICAL RESEARCH ASSOCIATION.

THE first annual report of the Clinical Research Association, Limited, is a satisfactory record of useful work. The Association was formed in September, 1894, its object being to assist medical men in the diagnosis and treatment of their cases by providing them with accurate laboratory reports on pathological products. At present there are more than 2000 members, representing every branch of medical practice, and the actual number of investigations conducted in the laboratory during the first twelve months after it was opened was 5227, including 1532 in the chemical department, 984 in the histological, and 2610 in the bacteriological. The chemical examinations related chiefly to urine and the bacteriological to pus and diphtheria exudation. Experienced attendants with instruments are sent to assist at necropsies. Subscribers of one guinea before the end of 1896 will, we are informed, be exempt from any further entrance fee and from any annual subscription and will have work done for them at the reduced scales charged to members. The offices of the Association are at No. 1, Southwark-street, London Bridge, S.E.

THE PREVENTIVE INOCULATION OF DOGS.

THE researches undertaken by M. Pourtalé in collaboration with Professor Jolyet regarding the preventive inoculation of dogs against hydrophobia do not appear to have excited much attention, although the subject is unquestionably one of considerable importance. It is certainly better to prevent an evil than to cure one, and if dogs can be rendered refractory to hydrophobia in the manner advocated by these investigators it would seem as though we were arriving within measurable distance of the annihilation of one of the most terrible of all diseases. The conclusions which M. Pourtalé came to were laid by him before the International Congress for the Advancement of Science in August last, and also before the Sixth International Veterinary Congress, held at Berne in the following month; but according to a communication which M. Pourtalé recently made to the Société d'Hygiène at Bordeaux the reception he met with was far from encouraging. The president of the section at Budapest, Professor Hutérat, while cordially recognising the academic merit of the work, was, nevertheless, of opinion that it was not necessary to take any further action with regard to it, and at Berné "the systematic opposition which has for years pursued all endeavours to establish the prophylaxis of hydrophobia" is likewise said to have been in the ascendant with the majority of the members of the congress. That M. Pourtalé was not entirely destitute of supporters is, however, clear from the following resolution, which was proposed as an amendment: "The Sixth International Congress of Veterinary Medicine, taking into consideration the major importance of the author's conclusions as to the immunising and curative inoculation of dogs against hydrophobia, expresses the hope that all persons engaged in experimental science will interest themselves in the verification and control of the tests upon which these conclusions are founded, with a view to the introduction into the various European states of preventive canine vaccination after the method indicated."

LONDON POST-GRADUATE COURSE.

THE daily classes in Bacteriology are now going on and the summer term will open on Monday, May 4th, to be followed by the summer vacation courses during the first fortnight in July. The classes will meet at Moorfields (Eyes), Blackfriars (Skin), Great Portland-street (Throat, Nose, and Ear), King's College (Bacteriology), Cleveland-street (General Medicine and Surgery), Institute of Preventive Medicine (Urine Testing, &c.), Parkes Museum (Hygiene), and classes in Pathology and other subjects will also be formed. The large number of practitioners who find themselves in London or who can spare the time to visit the metropolis will be able during the next two or three months to occupy themselves profitably. Early entries will materially assist in the formation of classes. A prospectus can be obtained from Dr. Fletcher Little, 32, Harley-street, W.

A NONAGENARIAN AMERICAN PHYSICIAN.

A RECENT number of the Philadelphia *Medical and Surgical Reporter* contained an appreciative obituary notice of Dr. Hiram Corson, who was born in Plymouth township, Montgomery county, Pennsylvania, on Oct. 8th, 1804, and died at the same place on March 4th in the present year. He received his diploma in medicine from the University of Pennsylvania in 1828 and the same year he established himself at Plymouth Meeting, where he continued in active practice for more than sixty-five years. It was not until a year ago that his advanced age compelled him to retire from work and he was then the oldest practising medical man in the United States. He was a member of the Orthodox Society of Friends and was conspicuous for his influence in the meeting at Plymouth. Dr. Corson was one of the first among American medical men to advocate the formal recognition of female practitioners. He was a frequent contributor to the *Medical and Surgical Reporter* from its commencement, and as recently as May, 1895, an article by him on Diphtheria and its Treatment was published in its columns.

A CORONER ON THE CONTAGIOUS DISEASES ACT.

THE coroner for West Surrey (Mr. G. F. Boumieu) held an inquest on April 15th at Godalming on the body of a young seaman who had hanged himself. Depression was clearly the cause, a letter the young man left containing the sentence, "Everything I do I cannot get right, so I think it is best that I were out of the world." The rest of the epistle—it was couched in pathetic language—dealt with family matters and arrangements. The young man who had been staying with his aunt and uncle was on leave from H.M.S. *Excellent* at Portsmouth and was to have been drafted to H.M.S. *Fox*. A medical man does not appear to have been

Digitized by Google

called, but a policeman who had examined the body stated that the deceased had "contracted a serious disease." Warrant-officer McDowell of Portsmouth said, in answer to a question from the coroner, that the men in the navy were greatly affected in this direction, the numbers being something appalling. While they were commissioning H.M.S. *Fox* on one day upwards of sixty men were rejected by the medical officers on this account—a remark which created what the reporter calls "sensation." The coroner, in summing up, urged the importance of the re-enforcement of the Contagious Diseases Act. There could not be any amelioration in the disgraceful and disgusting state of the army and navy, he said, until that step was taken. So deplorable a state of affairs as that which had been mentioned called for some supervision, and he thought nearly all of them agreed with him that it was essential that something should be done. The jury returned the customary verdict of "Temporary insanity."

COUNTRY HOLIDAYS FOR FACTORY GIRLS.

IT always gives us pleasure to call attention to the annual report of the "Factory Girls' Country Holiday Fund," of which the Duchess of Teck is patron. The report for 1895 marks the eighth year of the work of the fund and shows an increase in the number of girls sent away of 180 over the number for 1894. For an expenditure of £850 15*s.* 2*d.* 874 girls and women—whose individual holidays represent in the aggregate 1440 weeks—were enabled to leave their unhealthy surroundings and take up their residence in the country. To those who are compelled to spend the greater part of their lives amid the roar of machinery, among the noisome fumes of chemicals, standing for hours together at a bench or sitting with the head bent and the eyes ceaselessly straining to follow the work in hand, a week or a fortnight in the country means a new lease of life physically and morally. The Fund is a most deserving one, and we can only echo the wish that donations may so increase that the number sent away will each year "be supplemented without break until we attain the ultimate goal of our efforts—viz., that every girl or woman employed in the factories and workshops of this huge metropolis may be certain of obtaining a fortnight's recreation in the country."

DEATHS UNDER ANÆSTHETICS.

ONE of the gravest perils connected with anæsthesia is asphyxia due either to paralysis of the central controlling mechanism regulating respiration—a condition usually easily detected and remedied—or to some peripheral interference with breathing—e.g., spasm of the glottis, foreign bodies in the air passages, &c. In cases of empyemata where the abscess opens into a bronchus this danger is rendered acute. The patient is liable to be turned on the side for operative purposes and the pus coughed from the diseased side is aspirated into the lung of that side and in some cases even into that of the healthy side. This, coupled with the hampered condition of the heart from pressure or displacement, too often determines a fatal issue. Through the courtesy of Dr. Howard Green we record a case of death under the A.C.E. mixture followed by ether which exemplifies these remarks. The patient, a young woman aged twenty-five, was admitted to Charing-cross Hospital for relief of an abscess in her chest. The position of the abscess was not determinable by repeated acupuncture, and as the patient was rapidly losing ground it was decided to resect a rib and explore the chest. Her condition at the time of operation was critical. Hectic fever, progressive emaciation, and constant expectoration of foul purulent material existed. The empyema affected the left side and was believed to be of gastric origin. The patient was given the A.C.E. mixture (two drachms) as a preliminary to ether, and the chest was punctured. The second puncture drew pus. Resection of the rib was commenced, but the patient became asphyxiated from pus entering the air passages in large quantities. The amount of ether given was an ounce and a half. Artificial respiration was practised, but recovery did not take place. We are not told what position the patient was in when the operation was in progress.

BOARDS OF GUARDIANS AND THE VACCINATION LAWS.

THE severe object lesson enforced on the city of Gloucester in consequence of the guardians not carrying out the existing law as to primary vaccination should cause those boards who have for some time left this duty in abeyance to rescind their previous resolutions, which were to the effect not to enforce the law till the report of the Royal Commission was issued. In consequence of a letter addressed to the Wigan board of guardians by Mr. Berry, medical officer of health of Wigan, the following resolution was passed at their board meeting on April 17th, namely: "That the vaccination officers throughout the union be instructed to forthwith carry out the Vaccination Acts." It would be well just now for all medical officers of health to call the attention of their boards of guardians to the non-fulfilment of the law in reference to the carrying out of the Vaccination Acts and ask them to pass a similar resolution.

HOW DISEASE IS SPREAD.

THERE has lately been some correspondence on this subject in the *Standard* which is interesting in contributing to our knowledge of the great carelessness which some individuals exhibit as to the public welfare. The few cases that we hear of are, unfortunately, in all probability a very small proportion of those who actually travel in an infectious state. It would be well if individuals more thoroughly realised the far-reaching effects of illness and death which their selfishness or carelessness may lead to, and a severe penalty in all cases where carelessness in this matter has been proved should be inflicted. Of the cases which have been quoted, by far the worst example is that of a young woman who was sent from a London school when suffering from scarlet fever in order to save the school, and while in a highly infectious state is said to have travelled in at least three public conveyances. Under such circumstances the possibilities of the disease spreading are enormous and the only wonder is that so many people escape. We may also refer to some correspondence on "Cigar-ends" which has likewise appeared in the *Standard*. "A Smoker" recommends that all cigar-ends, &c., should be placed where they can be readily seen and picked up by poor people or that they should be collected and given away wholesale. Such a suggestion is to be most strongly condemned from most points of view, and more especially from the medical. Most medical men have seen diseases of the worst type accidentally acquired through drinking out of an infected cup or smoking an infected pipe, and to encourage the smoking of other people's cigar-ends is at the best to encourage a disgusting practice which may often end disastrously to those who indulge in it.

THE LATE BARON HIRSCH.

FROM Hungary comes the news of the death of Baron Hirsch, in his sixty-fifth year. The news will be received with profound regret by the social and sporting worlds in which the Baron was a distinguished figurehead, but by none will his death be more regretted than by those who have been the recipients of his charity, under which comprehensive heading fall all who have benefited by his munificence to the London hospitals. It is said that up to

Digitized by Google

the year 1891 Baron Hirsch had spent the extraordinary sum of £3,000,000 on objects of charity, and two years later it was announced that he had distributed a sum of about £42,000 among selected charities. In 1894 he caused £15,000 to be divided among London hospitals and charitable institutions, and last year the medical charities of London received from him donations amounting in the aggregate to £5000. His sympathy for the poor of his own faith is well known, and his scheme of colonisation will prove a lasting memorial of his name among the Semitic race; but the remarkable cosmopolitan character of the man is shown by the fact that he did not regulate his munificence by any considerations of race, colour, or creed, but distributed his wealth where he thought it was most required. All his winnings on the turf in gross amount, with no deduction for enormous expenses, were spent on objects of charity—he is said to have himself used the words, "I race for the London hospitals"—and it must not be forgotten that these winnings were often supplemented from other sources of his income. In 1894, when his winnings only amounted to £7500 he doubled the sum, and, as we have recorded above, gave £15,000 to London charities. Baron Hirsch will be sincerely mourned by the thousands who reaped the fruits of his wide benevolence.

MEDICAL MEN AND EVIDENCE IN DENTAL MATTERS.

AN action recently heard at the Cardiff county court opens up a point of interest as to the value of medical evidence on questions relating to dental surgery. In the case in question a registered dentist sued for the recovery of fees, the defendant putting in a counter claim for damages alleged to have been sustained in connexion with the operation performed by the plaintiff—namely, "scaling." In the course of her evidence the defendant stated that her mouth had been so injured that she was compelled to leave off her work, obtain a substitute, and eventually to call in medical advice. In support of this the medical man was called and stated that the condition of the patient's mouth might have been caused by dirty instruments, although he was unable to state whether or not it was due to any particular malpraxis on the part of the defendant. The judge commented on the evidence of this witness, finding that it showed unnecessary animus. We hope that here the judge was mistaken, but a second remark that fell from him deserves attention. The defence was practically a charge of malpraxis, and he said that a qualified dentist, practising specially as a dentist, should have been called to speak to this and not a general practitioner. We think that the very large majority of medical practitioners would prefer not to express anything like an expert opinion upon a question relating to the practice of dentistry, especially in connexion with a charge of malpraxis.

THE ANTI-VACCINATION CRAZE AT EASTBOURNE.

IT is important at the present time, when small-pox and rumours of small-pox meet us at every hand, that persons intending to proceed to our health resorts should be in possession of reliable information regarding the condition of the place selected. This is the tone which a correspondent takes in forwarding to us a copy of the *Eastbourne Chronicle* of the 11th inst. We find in its columns a short space allotted to a discussion of the vaccination question by the board of guardians. Miss Hall, one of the lady members, had the courage to bring forward the matter of the serious state of the town, there being vast numbers of unvaccinated children growing up in the place, and pointed out that as regards the infants born in 1894 only 10 per cent., and of those born in the succeeding year only 19 per cent., were returned as vaccinated. She laid stress on the prevalence of small-pox at Gloucester as calling for reconsideration of the attitude of the guardians towards their plain duty under the Acts, and drew attention to the dependence of the town on the large number of visitors who flocked there from time to time. But the matter was speedily quashed by others, and the raising of the question was deplored at the present moment *when the season was just beginning* and so soon after the scare about bad water. As to the latter point we now say nothing, but we do most emphatically advise all intending visitors to Eastbourne this year to get themselves re-vaccinated before going there, and to see that their children are protected at least by primary vaccination. With the inflammable material now in the place it behoves all who desire to stay at Eastbourne to secure protection.

A REPORT by the medical officer (Dr. W. R. Smith) of the School Board for London on the Prevalence of Diphtheria in London and Elsewhere, and its Alleged Connexion with the Elementary Schools, was presented to the Board on Thursday last. We must defer analysis of its contents until a later issue of THE LANCET, with the remark that its publication practically simultaneously with that of the Annual Report for 1894 of the medical officer of health of the Administrative County of London will serve to increase the interest of both reports.

MR. T. A. DE LA RUE, the chairman of the council of management of the Royal Chest Hospital, City-road, E.C., has sent a donation of 300 guineas towards the fund being raised in connexion with the festival dinner to be held at the Hotel Métropole on May 26th. The Right Honourable Lord Charles Bruce, P.C., president of the hospital, will take the chair on the occasion.

A MEETING was held on Tuesday afternoon at 20, Hanover-square, to consider the suggestion of the School Board that Dr. Glover and two others should meet the School Attendance Committee to discuss matters which affect the friendly relations of the profession to the board. The suggestion was accepted and arrangements were made for such a meeting.

MR. EDGCOMBE VENNING will preside at the annual dinner of the St. George's Hospital Medical School on Oct. 1st next. The introductory address will be given by Mr. Wm. Adams Frost, ophthalmic surgeon to the hospital.

WE understand that Dr. Wilks, since his appointment as President of the Royal College of Physicians of London, has resigned his seat on the General Medical Council as representative of the University of London.

THE French Academy of Medicine has decided to divide a prize of 25,000 francs between Dr. Roux of Paris and Dr. Behring of Berlin, in recognition of their joint work upon the antitoxic treatment of diphtheria.

THE annual dinner of the Army Medical Department will be held this year in the Whitehall Rooms of the Hôtel Métropole, London, on June 15th, 1896, at 7.30 P.M., the Director-General in the chair.

THE Queen has signified her gracious intention of subscribing 100 guineas to the fund now being raised for the re-endowment of Guy's Hospital.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XVII.

The Contemporary Medical Press. — Its Attitude towards THE LANCET.—*The Medical and Physical Journal.—Macleod v. Wakley.—Dr. James Johnson.—The Medico-Chirurgical Review.—Wakley v. Johnson.—The London Medical Repository.—The Medical Gazette.*

IT has been previously noticed that the interference of other medical journals had an exceedingly irritating effect upon Wakley. The virulent articles in the *London Medical Repository* had impelled him into continued litigation with Abernethy, and the narrow protests of the *Medico-Chirurgical Review* led to the strictures upon "hole-and-corner" surgeons, which resulted in the two lawsuits, Tyrrell *v.* Wakley and Bransby Cooper *v.* Wakley. It would seem at first sight that this susceptibility to criticism at the hands of the press betokened some weakness and inconsistency, as a man who gives hard blows himself ought to take punishment quietly. But this would not be quite a just estimate of the position. Wakley was a pugnacious man, and the advice of journalistic rivals for whose methods he had no respect only made him more resolute to go his own way. He did not wince under stricture, but he writhed under well-meaning advice. In the very early days of THE LANCET his inimical attitude towards the medical press had its only explanation in this proud and pronounced restiveness, but later the position became more serious. Wakley was set up by his brother editors as a bogey-man and a terrible example. Astounding lapses of truth and decency were attributed to him, and dark hints as to his past were scattered broadcast. A paper was specially subsidised by his opponents to run counter to THE LANCET, and it, like its older contemporaries, showered personal abuse upon Wakley. Language in those days was somewhat unmeasured, and Wakley's retorts were very strong, full-flavoured, and effective. The survival of THE LANCET while all its rivals have long since succumbed keeps Wakley's language on modern record, while that of his adversaries is lost to memory. The early numbers of THE LANCET in which this wordy warfare was waged—not, as will be seen, that the warfare always stopped at words—have often been reprinted and many libraries possess them. All interested in the history of medicine constantly consult them, and in so doing must happen upon some of the many contentious articles. It would be difficult for such readers to acquit Wakley of scurrility, but for the right understanding of him it is necessary to know something of those against whom he was fighting and to appreciate a little the measure of offence that he received. Also the license of the time must be insisted upon, for in the twenties and thirties what now seem the necessary amenities would have been regarded as mealy-mouthed hypocrisies.

There were three contemporary medical journals of some consequence published in London at the time that Wakley founded THE LANCET. These were the *Medical and Physical Journal*, the *Medico-Chirurgical Review*, and the *London Medical Repository*. The *Medical Gazette* followed almost immediately.

The *London Medical and Physical Journal* was founded in 1799 as the *Medical and Physical Journal*. The original editors were Messrs. Bradley and Willick, of whom fame has nothing to relate; but a new series was started early in the century under the editorship of Dr. Roderick Macleod. It was a decent monthly magazine of some ninety pages, with no particular reason for its existence. Its editor followed an easy conservative policy, and the bulk of its articles were translations from the foreign medical journals, with critical remarks appended, while long excerpts from scientific books were inserted as reviews. When THE LANCET was first started the *Medical and Physical Journal* ignored its existence—which looked like dignity. But in three years' time this policy became laughable, because all the profession were speaking of the revolutionary weekly paper of which the *Medical and Physical Journal*, addressed monthly to that profession, had no cognisance. This was very well at first. But later the *Medical and Physical Journal* became frankly imitative. Its circulation had waned, many of its subscribers having been seduced from it by the more spirited management of THE LANCET, and Dr. Roderick Macleod invited to his columns contributions from hospital officials. He proposed, in fact, to publish hospital reports as THE LANCET was doing. These reports, and, indeed, the whole of the journal, were subjected frequently to bitter criticism in THE LANCET. This was natural, and not due, it should be added, to any excess of journalistic rivalry. It was all in the way of fair rejoinder, for Dr. Roderick Macleod when he found himself compelled, if he desired at all to register public thought, to notice THE LANCET had been severe upon it and very high with Wakley. He had found fault with his taste in publishing hospital reports and the lectures of hospital surgeons. Then Dr. Roderick Macleod took to the same ill habit himself. It is true that Wakley published independent accounts of the medical and surgical proceedings of the day without asking permission from anyone, and that Dr. Roderick Macleod only published accounts sent to him by the different operators, but this was not a distinction with so much meaning as it would appear to have. The various hospital surgeons had found Wakley's action in publishing these reports to be wrong, not because their leave was not asked, but because they considered the publicity thus afforded to the doings within the walls of hospitals would militate against the interests of the profession. And Dr. Roderick Macleod's journal had approved of their view. In no uncertain terms he had declared the publication of lectures and hospital reports to be a monstrous breach of professional etiquette. Therefore, it was inconsistent of him to desire to publish these reports and to consent to be the medium through which they should reach the world, and it was this inconsistency that gave Wakley his opportunity of retaliation. He took it and unsparingly. The *Medical and Physical Journal* had a yellow cover and was termed a "Yellow Fungus," while Dr. Roderick Macleod's sonorous baptismal name was eternally introduced into the columns of THE LANCET and always in some ridiculous connexion. Either as Roderick the Goth, or as the Editor of the Gothic Absurdity, or as plain Roderick, he was made the perpetual object of a ferocious sort of joking. Dr. Roderick Macleod answered back, but he had neither the force of his adversary nor the same popular cause. Wakley was working for the profession at large and his methods, right or wrong, were consistent. Dr. Roderick Macleod, a member of the honorary staff of St. George's Hospital, represented his own order only and stood convicted of tergiversation. At last the strained relations brought the rival editors into a law-court. The dispute was an entirely trivial one, but so clearly was it inevitable that a judge would sooner or later be asked to decide between them that it was well for the reputation of both and for the after chances of peace that the quarrel had no serious origin. It arose out of a difference of opinion as to the merits of

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., and XVI. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, and 18th respectively.

Digitized by Google

what is now known as "Wardrop's method" of distal ligature for the cure of aneurysm. Dr. Macleod appears to have thought lightly of the method and published an account of "the dissection of one of the cases of aneurysm in which the artery was *supposed* to have been tied beyond the tumour," the object of the publication being to show that Wardrop's operation had failed in this instance. Wakley then published the alleged libel, which had been intended as a rebutting statement in Mr. Wardrop's behalf, who was a highly valued member of Wakley's literary staff. He pointed out that the patient on whom the post-mortem examination had been made had died from other causes entirely than aneurysm, so that it was unfair to speak of it as a case where Mr. Wardrop's treatment had failed, and went on to say that while Dr. Macleod was ready enough to publish what he thought was a failure he had omitted to publish a successful case which had occurred some months back. The accusation was that in his character as editor Dr. Macleod had been guilty of improper partiality. As a matter of fact Dr. Macleod *had* published the successful case and Wakley had overlooked it. The defence was that the comments had been made in fair rivalry and that an oversight had occurred. Mr. Brougham, who looked after Wakley's interests, was not instructed to offer any apology. The libellous paragraph alluded to was offensively worded, and this, coupled with the absence of all apology, caused the jury to award to Dr. Macleod £5 damages out of the £100 that he claimed. Dr. Macleod resigned his position as editor shortly after this case and became editor of the *London Medical Gazette* in 1827. The *London Medical and Physical Journal* ceased to exist in 1833.

The *Medico-Chirurgical Review* was edited by Dr. James Johnson, another of Wakley's contemporaries whose enmity to him was undoubted. Dr. James Johnson, an Irishman, was, like Wakley, the son of a farmer. He was born in 1778, and apprenticed at the age of fifteen to a medical man in Antrim. At the age of twenty he was appointed surgeon's mate in the navy, and later he served as full surgeon in the Egyptian campaign. It is worthy of note that at this time he possessed no diploma. In 1800 and 1801, being on leave, he studied at the Windmill-street School (Dermott's), where he was a very assiduous worker. He was appointed to another ship and cruised in the Northern seas, Greenland, and Hudson's Bay. On his return he again studied in London, as he did on his return from a second cruise, spending his prize-money in walking the hospitals. In 1806 he attended the lectures of Sir Astley Cooper with assiduity, and, possibly through that great man's boundless interest, was appointed to the *Impregnable*, Captain the Duke of Clarence, afterwards William IV. This was the turning point of his career. He became surgeon to the Duke, and at the peace in 1814, when Bonaparte was believed to have been safely relegated to Elba, settled down to practice at Portsmouth, where he was very popular with the Naval authorities. In 1816 he started the *Medico-Chirurgical Review*. This was at first called the *Medico-Chirurgical Journal*, and was published monthly in collaboration with two medical friends, but in 1818 he took over the whole liability and became the sole proprietor. He then changed the title of the periodical and transformed it at the same time into a quarterly. He wrote the greater part of his *Review* himself. This he was competent to do, for though largely self-taught he was a widely-read, able, and industrious man. In 1821 he took the degree of M.D. St. Andrews, at that time obtainable by decidedly lax methods.

This brief sketch of Dr. James Johnson, or Johnstone, as he later called himself, reverting to his correct patronymic, is necessary to the comprehension of some of the personal allusions to him. The *Medico-Chirurgical Review* at the time of the issue of THE LANCET enjoyed a large circulation and a good reputation. In the last number of 1823 Dr. James Johnson acknowledged the receipt of the early numbers of THE LANCET in terms which seem to have been intended to be amiable; but Wakley objected to their patronising ring, and what was intended to be a sort of welcome struck the first note of the future relations of bitter and prolonged quarrel.

"We hold it to be a breach of etiquette for one periodical publication to animadvert on the conduct of another unless attacked or interfered with itself," said the *Medico-Chirurgical Review*. "We mean, of course, medical journals, for political publications use no ceremony with each other. In offering a word or two of advice to our young friend The Lancet, and through him several others of our juvenile contemporaries, we trust they will not impute to us any unworthy motives, and that on mature reflection they will acknowledge the propriety of the advice we give .....

"We are convinced, then, that no medical periodical publication can succeed unless conducted on *unexceptionable* principles—we mean such principles as cannot be reasonably objected to by the members of the profession. We think that the unauthorised publication of a man's lectures as they are delivered from day to day cannot be defended on principles of morality, equity, or medical ethics, and therefore we advise our junior contemporaries not to take advantages of, or rely upon, a practice which can at best but afford a temporary interest. Secondly, we would dissuade them, if in our power, from mixing up politics, theatrical criticisms, and other heterogeneous matters with medical science or literature. It is an unnatural union which cannot long hold together, and has invariably failed hitherto in every instance where it was attempted. The above exceptions made, we wish every success to The Lancet and all other candidates for public favour; nor will we ever refuse to give whatever publicity they require through the medium of this journal."

The qualified proffer of friendship was rejected roughly by Wakley, who did not think that a quarterly *résumé* of things in the medical world, written in the interests of a few leading men, could be of any practical use to his revolutionary weekly print. The unceremonious manner in which Dr. James Johnson was told to mind his own business and try to obtain something readable for his own paper galled that hot-headed sailor, who seems at once to have made up his mind to demonstrate the good he might have been by the harm he could do. The following number contained an article headed "Property and Privileges of Lecturers, Hospitals, and Medical Societies Considered." It formed nearly six pages of forcibly written censure on the practice of publishing lectures, the writer challenging Wakley to produce a "single respectable testimony in favour of the practice," and saying "that the baleful influence of a private spy and public informer" will with "vampyre presence chill the current of communication between the preceptor and the pupil." This article defined the relations that were to exist between the rival editors, and for the next two years THE LANCET and Wakley were made the subject of the most unfavourable comments by Dr. James Johnson, while Wakley answered back in like vein. Each hit very hard. Dr. James Johnson was the elder—a man with an unblemished record, the friend of the heads of the profession, accepted by them as an exponent of medical thought, an officer of the two most important scientific societies then meeting in London, and a friend of Royalty; so he may be said to have carried heavy guns. On the other hand, his acquaintance with the leaders of the medical world hampered him by taking away from him his powers of free criticism, while his quarterly form of publication precluded him from any reply to attacks made upon him until, perhaps, three months had elapsed. Wakley's position was not in those early days so influential as that of Dr. James Johnson, but he got thirteen shots to one, and his ease in manœuvring gave him immense advantages over his adversary.

In the third year of the issue of THE LANCET came the

Digitized by Google

action-at-law that had been expected by everyone since the disputes began. Each side had been so profoundly abusive of the other that no one could guess who would be plaintiff and who defendant, but that legal proceedings were inevitable all could see.

On June 21st, 1826, the libel action of Wakley *v.* Johnson occupied the attention of the Chief Justice of the Court of Common Pleas and a special jury. The plaintiff was represented by Mr. Denman and Mr. Fitzroy Kelly; while the defendant retained two of the most noted members of Serjeants' Inn—viz., Serjeants Vaughan and Wilde. In the libel complained of Dr. James Johnson alluded to Wakley as an "outcast of medical society," who had been "accused of arson, convicted of libel, and cast in damages in a Court of Equity." These remarks alone would have been sufficient material upon which to base an action; but Dr. James Johnson, who had two long years of adverse criticism to answer, went further and elaborated his unpardonable phrase, "accused of arson." In the following sentence the cruel calumny of Argyll-street was raked up:—

"The threatened expulsion of Lucifer from the presence of the Gods on high Olympus," he wrote, "spread terror among the inhabitants of the lower regions; but happily they were spared a visit from this *firebrand*, or rather *fire factor*, as he is now generally denominated, who willingly, for once, made his exit from the postern gate."

This passage, which purported to describe a wholly imaginary movement on the part of certain infuriated members of the Royal College of Surgeons to expel Wakley from the gallery of the council chamber while he was speaking therefrom, was supplemented by an explanation of the term "Lucifer":—

"The common derivation of this word is wrong," runs the footnote; "it is not from *lux* and *fero*, but from *ignis* and *facio*. (*Vide* Secret Memoirs of the House of Argyll.)"

Mr. Denman made the most of the cruelty of these allusions, and of another in the same article in which the public were invited to consider "a new mode of lighting the streets without lamps and of extinguishing debts by means of fire-engines." He showed that the wicked rumours concerning the fire in Argyll-street which had been aroused by the withholding on the part of the company of the sum insured had been definitely disproved, that in a court of law no evidence whatever had been brought forward by the Hope Fire Assurance Company in support of the absurd suspicion, and that the Company had paid Wakley's claims in full.

The defence chiefly rested on Serjeant Vaughan's attempt to demonstrate to the court the known libellous proclivities of the plaintiff. Chief Justice Best paid no attention to this *tu quoque* argument (if argument it could be called), and in his summing-up said that there could be no doubt at all that the matter complained of was libellous. He instructed the jury, however, to take into account in assessing damages the aggravation and provocation which the defendant had received before he overstepped the bounds of legitimate controversy. The jury, after two minutes' consultation, found a verdict for the plaintiff for £100 and costs.

A second action brought by Wakley on the same day against the printer of the *Medico-Chirurgical Review* was settled by a compromise, Wakley being reimbursed all costs. After this action the war in words was continued for some time in both papers, but not with the spirit or bitterness with which it had opened. Eventually the quarrel died out. The *Medico-Chirurgical Review* had a longer life than the *Medical and Physical Journal*, for it did not cease to appear until about 1850, and THE LANCET interfered but little with its success from a business point of view. When it was apparent that no profit could come out of quarrelling both editors would seem to have decided to bury the hatchet.

The *London Medical Repository* was another quarterly medical journal, and was edited by Dr. James Copland, F.R.S., the author of the Medical Dictionary and a man of great scientific attainments. Dr. James Copland, who had himself with some success played the part of medical reformer, ranged his forces on the side of Wakley's foes, though he is said to have come into line with his fellow editors in opposing Wakley not through conviction but through the inadvertency of a sub-editor. As a consequence, however, of some words in slight of THE LANCET that appeared in the *London Medical Repository* that paper was nicknamed The "Mausoleum" by Wakley, and the dulness of its erudition and the staleness of its contents were weekly held up to ridicule. Dr. James Copland was a physician and a man of science, but no journalist. Nor did he want to quarrel. The quarrels were ready made when he blundered into them, and the abuse that he got was not directed personally at him, but at the causes that he was conceived to have espoused. His paper soon perished under the attacks of his foe and the successful rivalry of his friends, and he betook himself to the more congenial labour of writing his well-known dictionary.

Yet one more paper must be mentioned, as its life was longer than any of those to which allusion has been made, and its opposition to Wakley more distinct, more bitter, and more effective. This was the *Medical Gazette*.

The *Medical Gazette* first made its appearance in December, 1827, and in its address to its public avowed its hatred of and strenuous opposition to the policy of THE LANCET. The paper was started by Brodie, Abernethy, and other hospital surgeons, who bore a bitter and very intelligible grudge against Wakley, and Dr. Roderick Macleod left the *Medical and Physical Journal* to become its editor. Wakley declared that the only object of the paper was obviously to oppose, and if possible to ruin, THE LANCET, because THE LANCET had so ruthlessly interrupted the even tenour of the lives of the great men of the profession. The following passage from its preface denotes the attitude of the new paper towards the question of the publication of lectures and was accepted at once by Wakley as a formal declaration of war.

"A few years ago a set of literary plunderers broke in on the peace and quiet of our profession. Lecturers who had spent their lives in collecting knowledge, arranging it for communication, and acquiring the difficult art of oral instruction, saw the produce of their lives suddenly snatched from them and published for the profit of others, with the additional mortification of finding what they had taken so much pains with disfigured by bad English and ridiculous and mischievous blunders."

THE LANCET was not behindhand. The outward resemblance of the new newspaper to THE LANCET was very great, while all the editorial inspiration had been borrowed from Wakley. "Some despicable imitations of us have arisen," said Wakley, "and *stunk*, and become extinguished ..... one or two are still *emitting a little fœtor*." In the very first year of its existance the *Medical Gazette* published thirty more or less bitter attacks not only on THE LANCET but on Wakley, while for three years a steady fight was maintained between the rival papers. The *Medical Gazette's* method of attacking THE LANCET was fairly effective and very safe. Every week THE LANCET was searched for grammatical errors, solecisms, or failures in taste, and any treasure-trove was quoted as "wit," "veracity," "refinement," "good English," and the like. Later in its course, which was long and fairly successful, the *Medical Gazette* came into more violent contact with Wakley, but the account of this belongs to a later era. It was at first offensive but timid.

THREE YEARS OF MY LIFE UNDER THE SOUTHERN CROSS.

BY THOMAS LOWE LAXTON, L.R.C.P. EDIN., M.R.C.S. ENG.,
SURGEON TRANSVAAL STATE ARTILLERY.

LEAVING the River Thames by steamer on Nov. 9th, 1892, I arrived at Durban on Dec. 6th, and after spending a few weeks in that beautiful town I obtained the post of resident surgeon to Grey's Hospital, Pietermaritzburg, also in the colony of Natal. My patients here were of every race, nationality, and colour. The Kaffirs display marvellous recuperative powers after even the most severe injuries, especially of the head, their skulls being remarkably thick and dense; but when they are attacked by disease of an acute type their power of resistance compares most unfavourably with that of the whites. I was particularly struck with the frightful ravages that syphilis has made and is making amongst the natives, especially among the Zulus in Natal since the death of Cetewayo, under whose government the punishment for contracting syphilis was death either by impalement on a stake or burial alive. Pregnancy occurring in an unmarried female was also under the same regime punished with death. I noticed also that syphilis was virulent amongst the natives when it had been contracted from a white person and also among the white men infected by native women. Among the children of the natives scabies when neglected produces very severe effects, such as large suppurating sores, ulcerations of the skin, and general emaciation. After leaving Pietermaritzburg I spent six months at Barberton, where malarial fever is common, although neither so prevalent nor so severe in type as formerly. I then, in company with some friends, set out by waggon for Buluwayo in Matabeleland, which was then very little developed, but on arriving in the middle of June, 1894, at Pietersburg, a town in the north of the Transvaal and on the main road between Pretoria and Buluwayo, I found that military operations against the Kaffir chief Malaboch were in progress and that medical assistance was needed. I therefore volunteered my services, being anxious to see the Boers on the war-path, and to gain an insight into commando life and Kaffir warfare generally. The commandant-general, P. J. Joubert, of Majuba and Langs Nek fame in the English war, received me most courteously and I immediately went to the front. The enemy's position was on the top of a high mountain called Blaauwberg, and it took us four hours' hard climbing to reach it, but the labour was well repaid by the beauty and grandeur of the scenery. The campaign had been conducted with only partial success owing to the physical difficulties of the situation and to the unwillingness of the commandant-general to risk the lives of his men in attempts to rush the positions occupied by the rebels, but want of food and water compelled them to surrender during the last days of July, and early in August the camp was broken up and we returned to Pietersburg. Between thirty and forty were killed on the side of the Boers in this small campaign, besides several of the native allies.

[Operations were almost immediately resumed against a number of petty chieftains, including Modjaji (the celebrated "She" of Rider Haggard) and Magoeba. The latter held out the longest, but was killed about the middle of June, 1895.]

The natives are marvellously resourceful in their treatment of fractures, applying numerous small sticks closely woven together by string or stout grass and binding them firmly round the limbs after the fractured ends have been placed in apposition. Immediately after the termination of the campaign against Magoeba I was sent by the Transvaal Government as medical officer to the famous warm baths at Waterberg, some eighty miles north of Pretoria. This water has a very high reputation amongst the Boers, and I must admit, both from my own experience and that of others, that its medicinal properties are of no common order. I have seen marvellous effects produced by it in cases of gout, rheumatism, lithiasis, intractable neuralgias and neuroses, callous ulcers, wounds of long standing, and various forms of bone and joint disease, especially of a scrofulous origin. I have not been able to obtain an analysis of the water, but I am given to understand that it contains an unusually large proportion of lithia salts. The water rises abundantly and with great force and is nearly at the boiling point.

In the beginning of October of last year I was appointed surgeon to the State Artillery with the rank of captain, and for my services to the Government was made a full burgher of the Transvaal. Since then I have witnessed the defeat and capture of Dr. Jameson and his troopers at Doornkop, near Krugersdorp, particulars of which are so recent that I need not enter into details beyond stating that I was the Government medical officer placed in charge of the officers and men while prisoners in this country, and that all the wounded when sufficiently recovered were handed over to my care for transference to the Imperial authorities at the Natal border. Most, if not absolutely all, of Jameson's wounded were struck by Martini-Henry bullets, while the few burghers that were either killed or wounded—nine in all—were struck by Lee-Metford ammunition (Maxim gun or rifle). The majority of Jameson's men were wounded in the extremities. Fifteen received bullets in the right side of their bodies—namely, one in the jaw, two in the upper extremities, and twelve in the lower extremities. Eight were wounded in the left side, three in the upper extremities, and five in the lower. Three men were also wounded in the back and one through the bladder and intestines; of the remainder some were suffering from fractures, dysentery, abscesses, &c., and injuries not due to bullets. Three of the troopers underwent amputation—one above and two below the knee. Of the wounded burghers who were brought into hospital one had his brain traversed by a bullet, but nevertheless survived for ten days, one was wounded through the abdomen, one through the right lung, and one through both hand and lung; there were also five suffering from illness and injuries not caused by bullets. Considering the amount of ammunition expended by Jameson's column it is marvellous how few casualties occurred among the Boers—a result which was not due to bad shooting, but to the careful manner in which the burghers seek and obtain cover. Several of Jameson's troopers told me that the magazines of their rifles were practically useless, for the least portion of rust, dirt, or grit renders the mechanism unworkable; the rifles also became so hot that they could not be grasped with the hand, and some of the older men said that they longed for the Martini-Henry rifle which they had previously used.

IMMUNISATION AGAINST SERPENTS' VENOM AND THE TREATMENT OF SNAKE-BITE WITH ANTIVENENE.

BY T. R. FRASER, M.D., F.R.C.P.EDIN., LL.D.ABERD., F.R.S.,
PROFESSOR OF MATERIA MEDICA AND CLINICAL MEDICINE AT THE UNIVERSITY OF EDINBURGH.

PROFESSOR FRASER delivered an interesting address before the Royal Institution of Great Britain on March 20th. His subject was Immunisation against Serpents' Venom and the Treatment of Snake-bite with Antivenene, and the following is an abstract of his remarks:—

Traditions originating at a remote period and statements contained in the narratives of travellers—several of which were quoted—strongly suggest that human beings may acquire a power successfully to resist the toxic effects of serpents' venom. There is evidence, further, that venomous serpents are themselves protected to a considerable degree against their own venom and that of other serpents. These statements suggested to the lecturer the importance of experimentally investigating the subject, for if they were proved to be correct results would be obtained likely to be of value in the treatment of snake-bite in man. Some twenty years ago the collecting of venom was begun for this purpose, and soon facts were obtained which showed that by the administration of a succession of minute doses of venom animals became able to resist a lethal dose without any distinct injury. The first supplies of venom failed at this point and the investigation was not resumed until several years afterwards. In the meantime, the results of experiments on the toxines of disease had suggested to others that serpents' venom might, like those toxines, be able to produce protection in animals. Starting with Sewall's experiments of 1886, an account was given of the work of other investigators, until those of Phisalix and Bertrand, made in 1893, and of Calmette, made in 1894, were described. The lecturer chiefly used the

Digitized by Google

venom of the cobra of India in his experiments, but the leading experimental results obtained with it were reproduced with the venoms of several serpents of Australia, Africa, and America. The minimum lethal dose for a number of animals was first defined, and the protection was produced by a series of gradually increasing doses, until rabbits were able to receive, without injury, fifty times the minimum lethal dose, and in the course of five or six months a total quantity sufficient to kill 370 animals of the same species and weight. The blood-serum of these animals, called by the lecturer "antivenene," was next tested as an antidote, and having been found to be efficacious the limits of its antidotal power were defined in several series of experiments. The results appeared to justify the opinion that the antidotal action is a chemical and not a physiological one. The question—bearing also upon the antitoxins of disease—of the origin of this antidotal substance was discussed. In connexion with it the lecturer stated that he had found that by the stomach administration of antivenene, and more remarkably of cobra venom itself, an antivenomous substance could be introduced into the blood in a quantity sufficient to prevent death after the subcutaneous injection of more than the lethal dose of venom. Experiments were described in which from 500 to 1000 times the subcutaneous lethal dose of venom were introduced into the stomach of animals, and although no definite toxic symptoms were produced by these enormous quantities still the animals had become so far protected that within a few hours afterwards they were able to receive with almost no injury a dose of venom injected under the skin one-half larger than that which was able to produce death. These facts suggest that the antivenene is actually a normal constituent of the venom itself, and that the venom while in the stomach had been subjected to a process of analysis, whereby the poisonous constituents had failed to be absorbed into the body or had been destroyed, while the constituent or constituents which are antidotal had passed into the body in sufficient quantity to protect the animals against otherwise lethal administrations of venom. The measures to be employed in the treatment of snake-bite, including the administration of antivenene, were finally explained, and it was concluded that by its use human life could be saved in a considerable if not in a large proportion of cases that would otherwise terminate in death.

THE HISTORY, METHODS, HINDRANCES, EXPENDITURE, AND POLICY OF THE CIVIL RIGHTS DEFENCE COMMITTEE.

(Continued from page 1090.)

EARLY in 1894, on the initiation of the West Indian Alliance, the Civil Rights Defence Committee was formed. On March 5th a deputation of members and friends of the Alliance and of gentlemen not connected with the Alliance but who were interested in the successful vindication by Mr. Anderson of his own rights and in the establishment of the principles and rights of general and public interest to be upheld by Mr. Anderson in his appeals to the Judicial Committee of the Privy Council was organised to enlist the coöperation of the London and Counties Medical Protection Society in supporting Mr. Anderson and enabling him to prosecute the appeals to the Privy Council to obtain a reversal of the decisions in the cases of Marshall and Wife, Frank and Taylor. In reply to the deputation the London and Counties Medical Protection Society adopted resolutions that the decisions in the suit of Marshall and Wife *v.* Anderson are such as to seriously and unjustly affect the freedom of action of medical men in the practice of their profession and are matters of concern to all medical men, that it concerns the honour as well as interests of the profession to support the appeal of Mr. Anderson to the Privy Council, and that the proceedings in Trinidad were opposed to the absolutely assured rights of British subjects, and advised the nomination of a committee to issue an appeal to the medical profession. This led to the formation of a joint committee composed of members nominated respectively by the London and Counties Medical Protection Society and the West Indian Alliance, which issued invitations to public bodies to send representatives to the Committee, and in response to these invitations the British Medical Association, the West London divisions of the London and Counties Medical Protection Society and the Incorporated Medical Practitioners' Association, the West Indian Union, and the Trinidad and Dominica branches of the Union nominated representatives to the Committee. Shortly afterwards the Council of the Royal College of Surgeons of England also sent two representatives. The first appeal was issued by the Committee to about 1500 of the leading men in the profession, the amount of individual subscriptions being limited to 1 guinea. Subscriptions to the amount of £120 came in, and many strong expressions of opinion that the wrongs done vitally affected the honour and interests of the medical profession. After this, as further subscriptions came in slowly, Mr. Anderson, with the full approval of the Committee, appealed personally in August and September, 1894, to every Fellow of the College—about 1100 in number on the Register—bringing in about 35 guineas at a cost of £15 to £18. Some votes were passed by branches of the British Medical Association, and some subscriptions raised amongst members of branches. In April, 1894, Mr. Anderson gained the verdict of a Middlesex special jury for £500, Lord Coleridge entering judgment for the defendant on the ground that the action did not lie against a judge, and this judgment was confirmed in August by the Master of the Rolls, Lord Esher, and the Court of Appeal. When this judgment in Anderson *v.* Gorrie was pronounced by the Appeal Court, the Committee took this serious violation of Mr. Anderson's rights into consideration, and came to the conclusion that the best way of dealing with it would be by forming a new and powerful committee. The next important measure was the preparation of a formal report, under the title of an interim report, giving the investigations of the Committee and its conclusions with much of the evidence on which they were based together with the very strong opinions of the medical papers, professional public bodies, and professional men—an extraordinary weight of authority and opinion. The report was issued under the date Dec. 4th, 1894, but not struck off till later.

On Dec. 18th a printed letter from Lord Stamford giving a *précis* of the case and strongly appealing to the public for support was sent to two hundred and fifty leading newspapers in London and the provinces, but excepting a brief abstract in the *Times* and short notices in a few other papers it did not receive insertion or comment. Finding that the subject of judicial immunity was little understood or appreciated Mr. Anderson prepared with the approval of the Committee a short review of the subject with authorities, and it was published by the committee under the title of "The Doctrine of Judicial Immunity." Shortly afterwards "An Appeal to Public Men and Public Bodies" was prepared and published. Copies of the "Interim Report" "The Doctrine of Judicial Immunity," and "The Appeal to Public Men and Public Bodies," with a covering letter from Lord Stamford multiplied in the office, were sent to all the corporations and all the guilds, about eighty in number of the City of London, to every member of the House of Lords and House of Commons and to about 400 leading barristers, with apparently very little result either in moral support or funds. Just before the issue of the interim report THE LANCET had inserted a most earnest appeal for help in the work of the Committee and had opened a fund, heading it with a subscription of 10 guineas, but only one subscription of 5 guineas followed.

Efforts were next made to enlist the interest of some of the leading London papers. The *St. James's Gazette*, *Pall Mall Gazette*, and *City Press* consented to receive deputations headed by Lord Stamford. Upon this the *St. James's Gazette* and *Pall Mall Gazette* inserted an appeal from the Committee signed by Lord Stamford and many members, accompanied by a strong paragraph in support of the appeal. This resulted in a subscription of 10 guineas from a member of the jury who tried Mr. Anderson's action and a few other subscriptions also continued to flow in. As soon as Mr. Anderson became aware that when Lord Esher had adjudicated in his appeal Mr. Yeatman's action against Lord Esher was in progress he took legal opinion and was advised that the proper course was to move the Court to set aside the decision as voidable and to re-enter the appeal for hearing. Accordingly, at the end of July and beginning of August, 1895, he gave notice of his motions (1) to set aside as voidable the judgment of the Court of Appeal, and (2) on that motion being struck out of a motion to reinstate it in

Digitized by Google

the list, but this last was not even allowed to be placed on the list. During the short August Session of Parliament Mr. Anderson, by means of letters of introduction, interviewed many Members of Parliament and eventually succeeded in arranging a conference for Aug. 29th. The British Medical Association sent a shorthand reporter, and the Committee printed the report. The conference greatly strengthened the Committee and has been one of the causes of quickened interest in its work. As Mr. Anderson was placed in a very difficult and embarrassing position in applying to the Court of Appeal to constitute a court without Lord Esher the Committee invited the attendance of all members when Mr. Anderson's motion came on on Oct. 24th. Four were able to attend—viz., General Graham, Mr. Ross Clyne, Mr. Greenberg, and Mr. Rivington. This was a fortunate circumstance as the adverse decision of the Court of Appeal, which included the Lord Chancellor, might otherwise have alienated some of Mr. Anderson's supporters; but, as it is, the testimony of the delegates to the courteous but firm demeanour of Mr. Anderson in the face of a very trying ordeal has increased the general interest in his case.

In July, 1895, the Committee had published its second interim report, and at the end of the year the third interim report was issued giving many important press notices and carrying the work of the Committee up to date. The third interim report dealt also with the refusal of the Court of Appeal to hear Mr. Anderson's motions. It has since been enlarged and been issued as a second edition. Through the agency of General Graham the Committee were able to invite the coöperation and support of the Torquay Medical Society. Draft resolutions were suggested for adoption and also a form of memorial for signature soliciting the assistance of the Member of Parliament for that division. In response to this appeal the Torquay Medical Society gave a vote of £5 from its fund, raised £13 amongst its members, and obtained numerous signatures to the memorial to Captain Philpotts, its representative in Parliament. It also communicated its cordial good-will to the Devon and Exeter Medico-Chirurgical Society, which a little later voted seven guineas from its funds and twenty-two guineas were subscribed by the members individually. The members also memorialised their Member of Parliament. St. Mary's Hospital Medical School, where Mr. Anderson was a pupil, voted five guineas to the fund.

The next step, and one which brought great accession of strength, was a deputation inviting the Association of Fellows of the College to join the Committee. The proceedings, a short notice of which appeared in the *Times*, are given at length in the second edition of the third interim report. The Association appointed representatives on the Committee who have added to its working influence.

The forms of resolution and memorial above referred to were afterwards further elaborated and, with a draft letter to Members of Parliament, were submitted to the President and Council of the British Medical Association, and the same letter, resolutions, and memorial were sent to the constituent bodies. The Council of the British Medical Association at their meeting on Jan. 15th, 1896, resolved: "That a copy of the report of the Civil Rights Defence Committee be forwarded to the branches, together with copies of the resolutions and draft suggestions referred to." Six hundred copies of memorials to Members of Parliament, each with five of the letters inviting constituents, both lay and medical, to sign the memorials, have been delivered to the general secretary of the British Medical Association to enable the resolution of the Association of Jan. 15th, 1896, to be carried out. Several branches of the Association have passed the resolutions and are obtaining signatures to the memorials to their Members of Parliament. The course adopted by the Shropshire and Mid-Wales Branch and ably carried out by Mr. Cureton, the president, is one that affords the best prospect of success. Mr. Cureton addressed each Member of Parliament in the area of his branch, he interested the mayor of Shrewsbury, and he secured an admirable article in the *Shrewsbury Chronicle*. This, it is hoped, will be followed by the signing of memorials, both by medical men and laymen, in every division and borough in the area of the branch. It is very essential to secure the coöperation of medical men in obtaining the signatures of laymen. Few men are in a better position than medical men to do this, and at present the Committee, though obtaining other help when possible, has in few places anyone on the spot to whom it can personally appeal for help except medical men.

The forms of memorial have also been printed for general use by medical men and laymen throughout the United Kingdom, and many have been taken charge of by active friends for signature. Each member of the Committee has been asked to take charge of one and obtain signatures to it for the Member of Parliament in his district. A tabulated statement of the memorials which have so far been sent to Members of Parliament or are in course of signature is kept by the Committee, and every effort is made to keep these lists correct and complete up to date.

Special forms and invitations to convene public meetings in their constituencies were framed for Mr. Cohen, M.P. for East Islington, and Mr. Kimber, M.P. for Wandsworth, who had both expressed themselves strongly in favour of the objects of the Committee. The very energetic measures taken in East Islington are calling widespread attention to the matter and arousing general interest in that constituency. The executive committee of the Liberal Association received Mr. R. B. Anderson. He addressed them personally and the members as individuals signed the memorial to Mr. Cohen. The memorial has also been signed at the Mildmay Radical Club. In Wandsworth several invitations to Mr. Kimber to convene and preside at a public meeting have been signed.

Debates upon the questions arising out of Anderson *v.* Gorrie have taken place in the Hampstead Parliament and the Gray's-inn Debating Society. At the latter Mr. Copeland, Mr. Bellot, Mr. Degazon (of St. Lucia, British West India), and Mr. Pereira (of Ceylon) all delivered powerful speeches in support of a motion affirming the necessity, in the public interest, of appeal to the House of Lords in Anderson *v.* Gorrie. General Graham attended and spoke on behalf of the Committee. The motion was carried by a large majority. Mr. Bellot, who took part in the debate, has contributed an important article on the legal aspects of Anderson *v.* Gorrie to the *Westminster Review* in the numbers for March and April. He has reviewed all the previous cases in which actions have been brought against judges and has shown clearly that the doctrine of absolute judicial immunity has sprung up within the last few years.

Other efforts have been made by Mr. Anderson himself to inform the public mind and to arouse interest in the general community. Among these the following instances are deserving of record. Towards the end of 1895 very staunch friends of Mr. Anderson, Mr. and Mrs. Mann, the latter from Lincolnshire, proprietors of a large confectionery business, well acquainted with his family and himself in boyhood, very kindly afforded to Mr. Anderson an opportunity of addressing their operatives at their factory in the Wandsworth-road. The operatives are not combined in any organisation, but individually they were interested and most sympathetic. Mr. and Mrs. Mann and clerical staff took charge of memorials to their Members of Parliament and are obtaining signatures to them.

Early this year (Jan. 23rd) one of the fraternities of printers, or, as they are termed, the father and chapel of Messrs. Strangeways and Sons, printers, Tower-street, W.C., who had had their interest aroused in Mr. Anderson's case in the course of printing the various reports and issues of the Civil Rights Defence Committee, received Mr. Anderson. Mr. Williams, the father of the chapel, pointed out that the rights Mr. Anderson is defending are the rights of all. "They are," he said, "rights that we possess under Magna Charta and the Bill of Rights—and these rights, these great charters, are attacked and endangered in our courts." After an excellent speech from Mr. Anderson the following resolution was moved, seconded, and unanimously passed: "That this meeting of the employés of Messrs. Strangeways and Sons, printers, is of opinion that the judgment of the Court of Appeal reversing the verdict of the jury *given after a fair trial* in Dr. Anderson's case is subversive of the rights and liberties of the subject, and, with the circumstances under which it was given and upheld, demands the immediate and careful attention of Parliament as a public grievance before supply, and the punishment of all responsible; and the members of this chapel in meeting assembled pledge themselves to use what influence they possess with their representatives in Parliament to obtain a reversal of this illegal judgment." Twenty-two of the employés took charge of memorials all in separate divisions and have been obtaining signatures among the twenty-two constituencies. The chapel undertook to inaugurate a penny subscription throughout the trade numbering nearly a million and a half. If this subscription is successful it would bring in a considerable sum in defence of the rights involved in Mr. Anderson's case. The chapel have also delivered 500

Digitized by Google

copies of the memorials, with 500 copies of the third interim report and 1500 reports of their reception of Mr. Anderson, to delegates attending a great meeting of compositors at the Memorial Hall, Farringdon-street. This cost 13*s*., by post it would have been less effectively done for £4.

Other measures for insistance on the rights involved and for compelling the attention of public men and of Parliament are in progress. Mr. Anderson drew up a petition to the Queen praying for investigation and redress. After two well-attended meetings and very full consideration the Committee decided not in any way to fetter Mr. Anderson's discretion, and the petition has been sent in. A petition to the House of Commons has also been prepared praying for a vote in aid of the appeals and that the petitioners may be heard at the bar of the House of Commons.

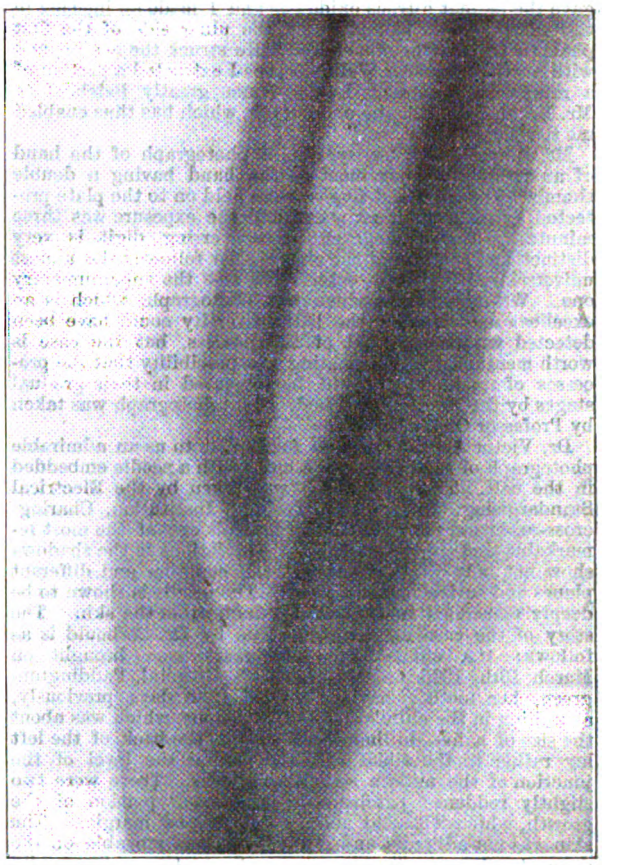
(To be continued.)

THE NEW PHOTOGRAPHY.

IN regard to the investigations made in THE LANCET laboratory there is little advance so far to report. We have made a few experiments with the modified process announced in our issue last week, but though in the case of the hand and fingers the requisite exposure is considerably shortened yet it does not appear to answer for thicker parts. It is curious, however, that prints are obtained at all, since the modification consists in placing the negative with the film side down upon fluor-spar. Mr. Strauss Collin of 15, Copthall-avenue, E.C., has placed at our disposal some new negatives which are said to produce images of the thicker parts of the body in five seconds, whilst excellent pictures of the arm, wrist, &c., with good detail may be obtained in a few seconds. So far as our experiments have gone the results have been to some extent confirmatory of this statement. The negatives are of thin zinc sheeting, upon which is placed the sensitive film, which, in addition to silver salt, probably contains a fluorescent substance. The development of the image is peculiar, the ultimate result being a positive resembling a ferrotype.

In response to numerous inquiries as to the apparatus necessary for obtaining good results we may state that all that is required is a focus tube of the pattern first designed by Mr. Jackson of King's College, and an induction coil giving a three-inch spark, and an accumulator such as that supplied by the Lithanode Company. The photographic plates should be specially rapid. The focus tubes are not so difficult to obtain as they were some weeks ago, and they are not quite so expensive now that several makers are supplying them. Messrs. Griffin and Co. of 22, Garrick-street, Covent-garden, W.C., have sent us a tube for trial costing 27*s*. 6*d*. It gives excellent detail and a fine sharp image with a few minutes exposure when placed at the proper distance above the negative. This distance should, whatever tube is being employed, be ascertained by use of the fluorescent screen, which will show at once the point at which the best definition is ensured. The tube submitted to us answered admirably with the potassic platino-cyanide screen. We have also had occasion to experiment with an induction coil supplied by this firm. It costs £9, and with a four-cell Lithanode accumulator gives nearly a four-inch spark discharge in air. It furnishes a very steady current when the contact-breaker or hammer is properly regulated, which may be done with ease and exactness by means of two screws. The coil is, in fact, just fitted for the requirements of the focus tube without exposing it to the risk of over-heating and probable destruction.

No new departure, save in brevity of exposure, enables us to give our readers illustrations showing that any marked development has taken place as far as medical and surgical utility is concerned. As many people are now employed in experimenting in radiography methods have become perfected, but that is all. We have had submitted to us a very great number of photographs. The one here reproduced was taken by Messrs. Brady and Martin, manufacturing and analytical chemists at Newcastle-on-Tyne. The patient was sent to them by Mr. Page, the precise nature of the injury to the forearm being at the time uncertain. As will be seen the new photography immediately revealed the site and position of the fracture, and the usual treatment was at once employed. We have reduced the negative submitted to us considerably in scale, but the illustration still shows the extreme utility that the process had. It has been our aim in the series of notices which we have written on the new photography to confine our attention almost entirely to cases where this practical utility could be ascertained. The Roentgen photography was only a curiosity in physics for a few days. The occurrence of the phenomena having been established, professional interest in them depends entirely upon their practical utility.



Messrs. Brady and Martin have also sent us a very good photograph of a needle buried in a patient's hand. The locality of the foreign body had not been ascertained until the photograph was taken, when it was immediately cut down upon and removed by Mr. Ingram of Newcastle.

Mr. Stanley Thomas, casualty surgical officer to the Middlesex Hospital, has sent us also a photograph which constitutes a good example of the success of the new process as an aid to diagnosis. He writes as follows:—"As an example of the great success of Professor Roentgen's method of photography as an aid to diagnosis, I think the following case may be of interest to the readers of THE LANCET. On Feb. 29th a woman aged twenty-six years ran a portion of a needle into her right hand; it entered the web of the hand on the palmar surface at the base of the ring finger. The patient came to the Middlesex Hospital on the evening of that day and was seen by Mr. A. E. Griffin, the house surgeon on duty. He could not detect the presence of the needle, and as the patient was suffering a considerable amount of pain he applied a hot boracic fomentation. I saw the patient afterwards daily and made several careful examinations of the hand, but could feel nothing, so the treatment of fomentations was continued on account of the pain, which was constant. There was no swelling, but the patient could not flex her finger. On March 10th she had her right hand photographed by Mr. Friese-Green, of King's-road, Chelsea, and the following day she brought the photograph to me and begged me to explore her hand. This photograph showed a distinct shadow across the proximal end of the first phalanx of the ring finger. I again examined the hand very carefully,

Digitized by Google

but could detect nothing, but as she was still suffering considerable pain and was unable to flex the finger I determined to make an exploratory incision and at the same time told the patient not to be disappointed if I found nothing, as I was still unable to feel any unusual resistance in the palm of the hand. I rendered the limb bloodless by an Esmarch's bandage and applied a tourniquet. Dr. A. H. Lister kindly gave the patient nitrous oxide gas and I made an incision in the palm parallel to and along the ulnar side of the first phalanx of the ring finger, the knife struck the needle, and with a pair of Spencer Wells' forceps I extracted a portion of a needle half an inch long. I am greatly indebted to Mr. Friese-Green for the photograph, which has thus enabled me to relieve my patient."

Mr. Robert Jones has sent us a photograph of the hand of an infant aged six months, the hand having a double thumb. The hand and fingers were held on to the plate protected by an aluminium sheet, and the exposure was three minutes. The photograph of the erring digit is very distinct and shows that the abnormality followed the almost universal rule that the outer digit was the supernumerary one. We do not reproduce the photograph, which is an excellent one, because the little diversity could have been detected without the aid of the process, but the case is worth mentioning as indicating the possibility that the processes of ossification could be observed in their gradual stages by the Roentgen method. The photograph was taken by Professor Oliver Lodge.

Dr. Victor A. Corbould has forwarded to us an admirable photograph of the left leg of a child with a needle embedded in the calf. The photograph was taken by the Electrical Standardising, Testing, and Training Institution, Charing-cross-road, and for precision of detail is one of the most remarkable that we have yet seen. Gradations in the shadows show not only the outlines but the contours and different planes and surfaces of the bones. The needle is shown to be deeply embedded in the calf an inch from the skin. The story of the case as narrated to us by Dr. Corbould is as follows: "A child aged two years was brought on March 16th, 1896, to the Children's Hospital, Paddington-green, her mother having noticed, two days previously, a swelling in the child's calf. The tumour, which was about the size of a five-shilling piece, was on the back of the left leg rather to the tibial side and was at the level of the junction of the middle and lower thirds. There were two slightly reddened patches over the lower portion of the growth, which felt solid and had ill-defined margins. The skin was not adherent and the growth was movable on the deep structures. There was no fluctuation. The child had complained of pain when her shoes were being put on and had sometimes fallen suddenly complaining of pain at this spot. About two months before Christmas she had suddenly cried whilst playing on the floor and was put to bed in the middle of the day because she seemed to be in pain. She slept well, but again complained of pain in the leg on being taken out of bed in the morning; however, during the course of the day she seemed to become quite well, and nothing was noticed except occasional falls associated with pain in the left calf until March 14th, when the swelling was first noticed. Thinking of the possibility of a foreign body having entered the limb I got the mother to bring the child on March 21st to Faraday House, Charing-cross-road, where a room had been specially fitted up for the purpose, and, with the kind assistance of Mr. H. H. Powles, an admirable illlustration was obtained by means of Roentgen rays. The original photograph is upon a whole plate—and two were taken in slightly different positions. The exposure of one was five minutes and the other six minutes. They show a needle lying deep to the gastrocnemius and between it and the soleus,[1] the fat investing the limb is also shown. From the appearance of the two photographs one was able to guess that the needle had had its eye broken off. Armed with these results on the following Monday a curved incision was made over the centre of the growth and the pointed end of a needle was seized with sinus forceps. I am indebted to Mr. F. Wallis (to whom the child was brought) for his kind permission to publish this case." The utility of the process in this case is indisputable.

Mr. Lynn Thomas of Cardiff has also sent us some interesting photographs which he has taken in illustration of the relative penetrability of the "x" rays through various tissues and other objects. One photograph is the right hand of a gentleman who had his right thumb torn off when he was two years of age. It shows that the epiphysis of the proximal phalanx was left, and also the two sesamoid bones of the flexor of the thumb. It is interesting to observe that the sardonyx in the gold ring on the ring finger allows the bone to be distinctly visible through it, and that its outline is on the same plane as that of the bone on either side of the ring. Upon another plate are shown three vermiform appendices removed from cases of perityphlitis. One of these had five fæcal concretions in it; they were fixed on a needle and appear black in the reproduction, probably from rust, because the only concretion not pierced by the needle is to be seen at the left end of the appendix as simply a darker impression than that of the appendix itself. A second shows the appendix enormously thickened, the wall being almost impenetrable to the rays, though the exposure was the same as in the previous example, where the wall was nearly transparent. The third is a distended appendix tied with silk at the right hand end. There is evidently nothing in it but fluid, and there is no impression left by the silk on the plate. Another object on this plate is a kidney with three calculi and débris in it. The kidney has not been incised, and the exact localisation of the calculi or even their existence is not very obvious. The last object on this plate is the most interesting. It is the gizzard of a cock laid open tranversely, having a needle in it projecting beyond it for half an inch. "This cock," writes Mr. Lynn Thomas, "during life was known as the 'one that cannot crow,' and from curiosity to find out the cause of his futile attempts at crowing I found that the explanation was the needle in his gizzard. It had penetrated the left lobe of its liver and was half-way out through the anterior abdominal wall. A little reflection upon the condition of the needle during the proud attitude assumed by the bird in crowing will at once explain the discomfort it felt." The third plate presents examples of various calculi. Five of them are vesical calculi, laminated, and formed of uric acid, urates, and oxalates. They are very opaque and there is no difference in their relative opacities. A sixth object is a renal calculus consisting of pure crystalline uric acid. This also is opaque up to its thin edge. A seventh is a little collection of gravel which had been passed per urethram. The last two objects are gallstones removed from the same patient, one from the gall-bladder and one from the ileum. The latter caused fatal intestinal obstruction, although it got through the bile duct without much trouble. The calculus removed from the gall-bladder is very interesting; the stone itself is almost circular and smooth externally, but in the negative there can be seen distinctly the concentric laminations of its structure as well as the faint radiating structure of the individual strata. Mr. Lynn Thomas's three plates form a very interesting record of work, for it is clear to everybody that the most practical development in the process that can take place to render the method of utility in our profession is work in the direction of ascertaining *the comparative density* of different structures.

Dr. Mackenzie Davidson has sent us some interesting reproductions of bullets within the cranium, showing that the vault of the skull is quite transparent to the "x" rays under an exposure of ten minutes or so.

[1] Owing to the difficulty of keeping the child quiet, spasm occurring during exposure, the outline of the needle is double.

PRACTICAL APPLICATION OF THE ROENTGEN RAYS IN SURGERY.

At a meeting of the British Laryngological Association, held on the 17th inst. at the rooms of the Medical Society, Chandos-street, Dr. John Macintyre of Glasgow gave an interesting address on the Practical Application of the Roentgen Rays in Surgery, with special reference to Affections of the Ear, Nose, and Throat. He related the history of his experiments in connexion with the employment of the "x" rays in the examination of the various parts of the body and showed on the screen the results of the advances made by him during the past three months. His first photograph, taken shortly after the publication of Roentgen's paper, was obtained after an exposure of forty minutes, and the last with an exposure of only half a second. He desired to emphasise the title of his address, as the most important use of the rays in surgery had been overlooked, as it was not so much for the purpose of photography that it ought to be employed, but for the examination of the various parts of the body by means of cryptoscopic screens, the use of which was demonstrated to the audience. Thanks to the advice and valuable assistance of Lord Kelvin and Mr. Bottomley of Glasgow University Dr. Macintyre has

Digitized by Google

been able to determine the best apparatus for the purpose. Firstly, secondary cells, with a current of from six to eight volts and from four to six ampères were necessary; secondly, a coil giving a spark of from two to three and a half inches; and thirdly, a good Crookes's tube which he considered the most important element, as improvement in results would be according to improvement in these tubes. He found that the best results were obtained by a tube of Newton's shape, in which the vacuum residue is about $\frac{1}{1\frac{1}{7}}$th of a million, the kathode consisting of a concave piece of aluminium, and the torrent passing directly across to the anode, which consists of a small disc of platinum placed obliquely, from which arise the "x" rays diverging in all directions. He had overcome the difficulty of the fatigue spot, or dark area, on the surface of the tube of which so many investigators have complained, by carefully heating the tube on the flame of a spirit lamp before the current was turned on. The best cryptoscope he has found was a sheet of paper evenly stretched on a wooden frame, and coated with a mucilaginous solution of barium or potassium platino-cyanide, preferably the latter. He had used the calcium tungstate, which is less expensive, but not with so satisfactory results. Dr. Macintyre showed on the screen photographs of nearly all the bones and joints of the living body including the deeply seated hip-joint. The cancellated structure of the bones of the hand was shown in a beautiful photograph taken with an exposure of six seconds. Photographs of the internal ear showing the semi-circular canals, the mastoid cells, and the ossicules were thrown on the screen. The lecturer described a case of a boy who six months previously had swallowed a halfpenny and had ever since complained of pain in the region of the cardiac end of the stomach with some difficulty in swallowing. On looking with the cryptoscope at the situation indicated by the pain nothing abnormal was detected, but on proceeding upwards the halfpenny was found impacted in the gullet on the level of the fourth dorsal vertebra, and a well-defined photograph of this case was shown, in which the ribs, spinal column, and the halfpenny could be distinctly seen. A case illustrating the use of the fluorescent screen in differential diagnosis was mentioned. A woman into whose middle finger some time ago a needle entered complained of pain at the point of the finger and insisted that the needle was still lying there, but it could not be detected by ordinary examination. On employing the cryptoscope, however, indications of periostitis of the terminal phalanx were observed and the needle was discovered in the tissues above the level of the wrist, the patient being convinced of this only when she saw the photograph. Dr. Macintyre had taken over 300 photographs. He objected to the introduction of new terms for the photographic results of the "x" rays, believing them to be vibrations in the luminiferous ether beyond the ultra-violet rays, and therefore the chemical effects on the sensitive film must be distinctly photographic in character. He spoke of the penetration of the rays and the methods he had adopted for obtaining the best definition and showed a photograph of the inner aspect of the right side of the skull with the courses of the meningeal vessels distinctly indicated and without any blurring although the rays passed through the other half of the skull, this result being attained by determining the penetration by length of exposure, distance of the tube from the part, and focussing by means of the cryptoscope. The most important advance, however, made by the lecturer was in photographing some of the soft parts as observed in a representation of a living larynx in which the tongue, the entrance to the œsophagus, the epiglottis, the cartilages of the larynx, and the hyoid bone were perfectly defined in various degrees of density according to their structure. By means of a small cryptoscope covered with a thin sheet of aluminum Dr. Macintyre had been able to see the antrum of Highmore as well as the roots of the teeth in the upper and lower jaws, and he showed a photograph in which erosion was distinctly visible in a case of cancerous disease of the upper jaw. He demonstrated the use of his cryptoscopic screens by passing the rays through the body of a boy, and the audience could distinctly see the ribs, spinal column, shoulder girdle, &c. Dr. Macintyre uses ordinary photographic plates, but by improving the Crookes's tubes he hopes soon to produce instantaneous photographs by the "x" rays.

Note.—Dr. Macintyre telegraphs that since his return to Glasgow he has obtained a distinct image of the bones of the hand "with one flash in the tube from a single interruption of an eleven inch spark coil," thus reducing the exposure to an exceedingly minute fraction of a second.

THE MIDWIVES REGISTRATION BILL.

A WELL-ATTENDED and influential meeting of the medical profession of Sheffield and its neighbourhood was held at the Medical School on April 16th, Dr. Dyson, senior physician of the Sheffield General Infirmary, being in the chair. The meeting was called to consider the above Bill and what steps ought to be taken with regard to it. A large number of the practitioners present took part in the discussion, and, as the outcome of the meeting, the resolutions, of which the following are abstracts, were carried unanimously.

1. That no legislation should take place until the General Medical Council and other public legalised medical bodies, and also the medical profession at large, have had full time to consider and opportunity to suggest amendments. Evidence on the subject has hitherto been taken somewhat too exclusively from special societies in London and elsewhere, and a truer view of the case would be acquired by obtaining also the opinion of general practitioners and of Poor-law medical officers.
2. That every Bill for the registration of midwives hitherto brought forward has proposed to institute what would, in reality, be a new and inferior class of medical practitioners, thus interfering with the beneficial operation of the Medical Acts by the licensing, in a most important branch of practical medicine, of, in our opinion, insufficiently trained and badly qualified persons.
3. That when it is stated that midwives are to have sole charge of cases of "natural labour" only, the expression made use of is very misleading, for a labour, apparently at first quite "natural," may suddenly become complicated and dangerous, and the fact needs emphasising that the heavy mortality amongst women during childbirth is by no means chiefly due to ignorance and mismanagement, as is sometimes asserted, but largely to "natural" causes, which can only be guarded against by superior skill. Well-regulated and prolonged study is absolutely necessary for those undertaking sole charge of any labour, and the short and perfunctory preparation and examination of women seeking to become midwives, too frequently practised of late, can be no adequate guarantee of their fitness for such grave responsibilities.
4. That the portals of the medical profession are now thrown open to both sexes—therefore that, after adequate study and authorised examination, women have now exactly the same opportunity for practising midwifery as men.
5. That we are prepared to support a measure for the registration of midwifery nurses, who shall attend confinements only under the control of fully qualified medical men or women, but never be entrusted with sole charge and responsibility.

A large general committee and an executive committee were appointed to take steps to bring the foregoing resolutions to the notice of the Members of Parliament of the city and district, and to as many other Members as possible, with a view to their being persuaded to take action, and not to allow any hasty or ill-considered legislation to take place in connexion with a question of such vast importance to the public in the first place, and to the medical profession in the second.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Marylebone Sanitary District.—This district is at the present time, Mr. Wynter Blyth observes, thanks in no small degree to the outbreaks of small-pox which have occurred within its limits, as well protected by vaccination as any part of London. We are glad to hear this, and we trust that other districts will not fail to profit by the experience which Marylebone has had. Mr. Blyth, in referring to the necessity for ample cubic space in fever hospitals, observes that it is a debatable point whether it is not better to temporarily curtail such cubic space than by insisting upon a liberal allowance to necessitate the retention of many patients in crowded tenement houses. It is difficult to decide a point of this nature, and it could probably only be discussed with profit in relation to the operations of a given hospital and district. If the reduction of cubic space minimises the chances of recovery of patients already in hospital and increases their tendency to septic complications and the contraction of other infectious diseases, we should say that a grave responsibility would rest upon the medical superintendent who permitted the "overcrowding"; but, again, there is the question of reduced chances of recovery to patients left in the tenement houses to be considered. Mr. Blyth, in discussing the hospital accommodation of the metropolis, refers to the fact that for two years the Marylebone vestry established and maintained temporary hospitals for infectious disease, but as no other

Digitized by Google

local authority followed the example set by Marylebone the vestry declined to maintain another hospital. Typhoid fever showed an increase in Marylebone in 1895, and Mr. Blyth thinks it not improbable that owing to the prolonged frost some local pollution of the water-supply may here and there have occurred. There is in Marylebone a large number of workshops, and Mr. Blyth reports that it is impossible for all of them to be properly inspected with the staff at his disposal. He thinks it may be desirable to add a lady inspector to the staff as there are several places in the parish which cannot be conveniently or decently supervised by male officers. The supervision of the milk traffic in Marylebone seems of a very thorough nature, or at least so far as the present legislative interference goes. To prevent any evasion of justice lay agents have been freely used for the purchase of samples, which, by the way, are collected extensively in the streets on Sundays and holidays and at an early hour in the morning, while inspectors have, on complaint, attended at private houses and taken milk on delivery. Mr. Blyth points out that the greatest adulterators are not the residents or tradesmen of the district, but itinerant vendors who hawk milk about the poorer parts. The supervision which is exercised in Marylebone seems, however, to be driving this species of milk vendor to other districts where the officers are more lax.

Chelsea Urban District.—Dr. Louis Parkes reports that the general death-rate of this district for 1895 was 19·28 per 1000, as compared with a rate for London as a whole for the same period of 19·86. The Chelsea rate is in excess of that for 1894, and Dr. Parkes states that the excess is in large part attributable to the return of influenza and to diarrhœal diseases. The most noticeable feature in the sanitary history of Chelsea during 1895 was the prevalence of scarlet fever, the figures for this disease showing an excess of 30 per cent. over those for London as a whole. There were in all 623 cases notified, and of these 57 occurred in the Duke of York Royal Military School and 41 in the Chelsea Workhouse and Infirmary. Dr. Parkes alludes to the difficulty which arose in the removal of cases consequent upon the demand upon the accommodation of the Asylums Board, and he states that some secondary cases arose where there was delay in removing the initial cases or when removal did not take place; but he observes that the exceptional incidence of scarlet fever in Chelsea is not to be explained by this inability of the Asylums Board, inasmuch as other districts suffering under a similar disadvantage exhibited no such excess. Dr. Parkes makes an interesting comparison of the vital statistics of the Chelsea home district with the detached portion of Kensal-town, and he shows that in regard at least to the five years 1891–95 the average standard of public health in Kensal-town was superior to that of the home district. Both its general and zymotic death-rate are lower. During 1895 there was an increase of 10 per cent. in the number of houses on the constant water service, but, as Dr. Parkes remarks, the whole of the home district should be receiving a constant supply.

Thingoe Rural District.—Dr. C. S. Kilner reports that during the year 1895 he found two boys who were engaged in milking cows desquamating freely from scarlet fever, their parents being ignorant of the nature of the disease from which they had been suffering. It would have been interesting could the distribution of the milk drawn by these boys have been traced, as presumably they must have been engaged in milking on repeated occasions while undergoing desquamation. If the milk-supply from this source was a large one the evidence would have been of value, even if only from a negative standpoint. In reference to the subject of disinfection under the provision of the Infectious Diseases (Prevention) Act, 1890, Dr. Kilner states that for the future he will not consider a house to have been disinfected to his satisfaction unless the process has been carried out by a competent person such as the inspector of nuisances.

Westminster Sanitary District.—Dr. J. Norton supplies in his report a good example of the difficulties which are experienced in practice with respect to infectious diseases as conveyed by tramps. He states that in a case of small-pox which occurred in a common lodging-house in his district the patient had slept in no less than five different places since he had noticed the rash on his body; and in another instance the patient, after the rash was observed, ran away and was only captured with difficulty. Owing to some alleged overcrowding in one of the Peabody Buildings investigations were made into the matter, and although the allegation was apparently unfounded, inquiries in respect to some Salvation Army shelters in the same district led to the discovery of considerable overcrowding and defective ventilation. Dr. Norton bears testimony to the good spirit with which his suggestions were received and to the prompt manner in which they were carried out by authorities.

Whitechapel Sanitary District.—Mr. Joseph Loane refers to the difficulty of arriving at anything like an accurate estimate of the population of his district, owing to the disturbing influences of immigration, &c., which obtain in it. He, however, roughly estimates the population at 79,000. The birth-rate of the district for 1895 was 39·3 per 1000, as against a metropolitan rate of 30·4 per 1000. The general death-rate was for the same period 22·8, as against 19·7 for the metropolis. The infantile mortality was 154 per 1000 registered births, as against 165 for London. Referring to the delay which was experienced in July and in September in procuring the admission of patients into the hospitals of the Asylums Board, Mr. Loane observes that in 35 cases 3 applications were made, and in 25 cases 4, while in 1 case as many as 11 are recorded. At the same time, Mr. Loane wishes to emphasise the fact that the officers of the Board showed as far as possible every consideration for the necessities of the district. He suggests that an increased accommodation for convalescents would render the existing beds more frequently available for acute cases. In reporting upon the outbreak of small-pox which occurred in Whitechapel during the year under review Mr. Loane states that 50 per cent. of the cases were reported to have come from the Salvation Army shelters, 25 per cent. from private houses, and the remainder from registered common lodging-houses, the Whitechapel Infirmary, and outside philanthropic shelters. Mr. Loane, in referring to the registered common lodging-houses, draws attention to the very thorough manner in which their inspection is carried out by the London County Council. Whitechapel contains a large number of philanthropic shelters, there being four belonging to the Salvation Army and eight to other bodies. The common lodging-houses are registered to accommodate 5612 persons and the model dwellings in the district have a population of 13,778. Mr. Loane proposes to discuss in a subsequent report the public health aspects of these model dwellings.

Coventry Urban Sanitary District.—Considerable improvements in matters calculated to affect the public health took place in Coventry during 1895. A second source of water-supply was provided, electric light was installed, and the tramway system, which, as Dr. Mark Fenton observes, will tend to distribute the population over a wider area, was extended. There has been during recent years in Coventry a steady decrease in lung diseases other than phthisis, and Dr. Fenton considers the diminution in all probability due to an alteration in the character of the population rather than to meteorological influences. He observed that the operatives in the cycle industry, who have largely supplanted the weavers and watchmakers, are not employed under such untoward conditions as were the latter. Attention is drawn in the report before us to the dangerous practice of sending school children to inquire as to the absentees. Dr. Fenton states that he has known infectious disease to be contracted in this manner, and the practice, he adds, continues in spite of his having warned the managers of its dangers. The condition of urban populations as to vaccination is at the present time a matter of interest, and the figures embodied in Dr. Fenton's report are worth recording. In 1889 no less than 96 per cent. of the infantile population were vaccinated, but since that year the following percentages represent for each year the state of affairs—89, 39, 7·6, 7·2, 7·7, and 4·5. The Coventry guardians are at the present time, in common with not a few other Poor-law authorities, as Dr. Fenton remarks, awaiting the report of the Royal Commission, and a grave responsibility rests upon the members to complete their labours. It is, however, some consolation to learn from the Coventry report that Dr. Fenton has advised the erection of a separate small-pox hospital.

Surbiton Urban District.—In discussing the prevalence of diphtheria in Surbiton during 1895 Dr. Owen Coleman states that sanction was given him to arrange for a supply of antitoxin to all who might apply for it and also to provide bacteriological examination in cases where this was necessary in order to assist the diagnosis. Dr. Coleman supplies a table in his report showing that the fatality-rate of diphtheria in his district has during the last six years varied from 6·2 per cent. to as much as 47·6, facts which it will be well to hold in view in inferring the effect of any actual or

Digitized by Google

supposed remedies. In the matter of scarlet fever Dr. Coleman gives some interesting instances of undetected and consequently unnotified cases of that disease which tend to show the limitations which with lay diagnosis must perforce obtain in practice to the advantage of compulsory notification. It would seem that the only means of reducing these cases is by educating the public as to the necessity of seeking medical advice and by instituting periodical examination of school children. Referring to the severe frost of February and March, 1895, Dr. Coleman draws attention to the fact that although in his district the absence of water led to numerous olfactory nuisances there was no excessive amount of illness due to this cause; there was not any increase of enteric fever during the period of frost. As Dr. Coleman observes, this absence from illness may possibly have been due to the fact that the excessive cold killed or at least arrested the activity of both putrefactive and pathogenic organisms.

Stoke-upon-Trent Urban Sanitary District.—Dr. Samuel Johnson records with satisfaction the fact that many important measures have been adopted for the protection of the potters. Overalls are now used by all workers in dust and glaze, and mess-rooms have been provided for those employed in the lead department, who are also compelled to wash before taking food. The use of respirators is still optional, but they are provided gratuitously.

Haydock Urban Sanitary District.—Dr. T. E. Hayward has estimated the population of his district by the three methods which may be employed for this calculation and the results are of interest. By the method adopted by the Registrar-General he estimates the population at 6843; by calculating the number of inhabited houses and the average number of inhabitants per house the figures 7791 are obtained; while estimating it upon the birth-rate the population is found to be 7884. It will be observed that the last two methods yielded nearly identical results, and Dr. Hayward has taken 7800 as the population. In reference to puerperal fever Dr. Hayward supplies figures to show that during the ten years 1885–94 the mortality-rate among women in childbirth in Haydock has been twice as great as for England and Wales. The township of Haydock is supplied with water direct from the Rivington reservoir of the Liverpool Corporation, but in the event of a breakdown in the main there are two storage reservoirs for supplying Haydock in the interval. Dr. Hayward states that as one of these reservoirs is uncovered and the ground in its neighbourhood is manured with privy midden contents pollution of the water in the reservoir is not altogether unlikely to occur. It seems, too, that the water during storage tends to deteriorate, and Dr. Hayward advises that when the direct supply from Rivington is cut off and it is necessary to use the water from the reservoir in question it should be boiled before use.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 7092 births and 3952 deaths were registered during the week ending April 18th. The annual rate of mortality in these towns, which had been 18·3 and 20·0 per 1000 in the two preceding weeks, declined again last week to 19·0. In London the rate was 19·4 per 1000, while it averaged 18·7 in the thirty-two provincial towns. The lowest rates in these towns were 11·1 in Swansea, 12·1 in Brighton, 12·8 in Croydon and in Preston, and 14·6 in Portsmouth; the highest rates were 21·2 in Bolton, 21·5 in Salford, 21·9 in Sunderland, 22·0 in Liverpool, and 25·2 in Birmingham. The 3952 deaths included 635 which were referred to the principal zymotic diseases, against 615 and 666 in the two preceding weeks; of these, 252 resulted from measles, 206 from whooping-cough, 66 from diphtheria, 48 from diarrhœa, 35 from scarlet fever, 27 from "fever" (principally enteric), and 1 from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Swansea, Preston, and Huddersfield, and the highest rates in Bolton, London, Salford, Birmingham, and Birkenhead. The greatest mortality from measles occurred in London, Plymouth, Norwich, Oldham, Sunderland, and Birkenhead; from whooping-cough in Bradford, Cardiff, London, Birmingham, and Derby; and from "fever" in Wolverhampton and Salford. The mortality from scarlet fever showed no marked excess in any of the large towns. The 66 deaths from diphtheria included 42 in London, 8 in Birmingham, 4 in West Ham, and 3 in Manchester. One fatal case of small-pox was registered in Leeds, but not one in London or in any other of the thirty-three large towns. There were 16 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 18th inst., against 33, 23, and 21 at the end of the three preceding weeks; 4 new cases were admitted during the week, against 2, and 5 in the two preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2527, against 2744, 2676, and 2587 on the three preceding Saturdays; 201 new cases were admitted during the week, against 224, 186, and 226 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 270 and 301 in the two preceding weeks, further rose to 328 last week, but were 56 below the corrected average. The causes of 58, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Oldham, Newcastle-upon-Tyne, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Norwich, Liverpool, Sheffield and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·7 and 19·7 per 1000 in the two preceding weeks, declined again to 19·0 during the week ending April 18th, and corresponded with the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·2 in Leith and 11·8 in Greenock to 22·6 in Aberdeen and 24·3 in Paisley. The 554 deaths in these towns included 21 which were referred to whooping-cough, 11 to diarrhœa, 9 to measles, 7 to scarlet fever, 7 to "fever," and 1 to diphtheria. In all, 56 deaths resulted from these principal zymotic diseases, against 61 and 91 in the two preceding weeks. These 56 deaths were equal to an annual rate of 1·9 per 1000, which was 1·1 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 21 and 29 in the two preceding weeks, declined again to 21 last week, of which 10 occurred in Glasgow and 5 in Aberdeen. The deaths referred to measles, which had increased from 6 to 20 in the three preceding weeks, declined to 9 last week, of which 7 occurred in Glasgow and 2 in Dundee. The 7 fatal cases of scarlet fever showed a further slight increase upon the numbers recorded in recent weeks, and included 2 in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. The deaths referred to different forms of "fever," which had been 4, 6, and 12 in the three preceding weeks, declined to 7 last week, of which 3 occurred in Glasgow and 3 in Edinburgh. The deaths from diseases of the respiratory organs in these towns, which had been 87 and 110 in the two preceding weeks, were 109 last week, and were 23 below the number in the corresponding period of last year. The causes of 34, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·5 and 25·4 per 1000 in the two preceding weeks, further declined to 20·6 during the week ending April 18th. During the past three weeks of the current quarter the death-rate in the city has averaged 23·8 per 1000, the rate during the same period being 19·2 in London and 16·6 in Edinburgh. The 138 deaths registered in Dublin during the week under notice showed a decline of 32 from the number in the preceding week, and included 6 which were referred to the principal zymotic diseases, against 8 and 10 in the two preceding weeks; of these, 4 resulted from scarlet fever, 1 from whooping-cough, 1 from "fever," and not one either from small-pox, measles, diphtheria, or diarrhœa. These 6 deaths were equal to an annual rate of 0·9 per 1000, the rate during the same period being 4·0 in London and 1·5 in Edinburgh. The fatal cases of scarlet fever, which had been 2 in each of the three preceding weeks, rose to

Digitized by Google

4 last week. The mortality from whooping-cough and from "fever" corresponded with that recorded in the preceding week. The 138 deaths in Dublin last week included 17 of infants under one year of age, and 42 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a slight further decline from the numbers returned in recent weeks. Six inquest cases and 7 deaths from violence were registered; and 48, or more than a third, of the deaths occurred in public institutions. The causes of 5, or nearly 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR KAVANAGH has been posted to the North-Western District. Surgeon-Major Fayle has been transferred from Canterbury to Shorncliffe and Surgeon-Major Harran to Tipperary. Surgeon-Major Braddell and Surgeon-Captain Harris have arrived in Egypt. Surgeon-Captains Josling and Hosie have embarked for the West Coast of Africa and Surgeon-Captain Lavie for Egypt. Surgeon-Captain Browning has been posted to Limerick.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain W. E. Jennings is appointed to act as Health Officer of the Port of Bombay pending the return of Surgeon-Major F. F. MacCartie. Surgeon-Major J. Crimmin, V.C., is appointed to act as Port Surgeon, Aden, vice Surgeon-Major W. P. Carson, proceeding on leave. Surgeon-Captain G. C. Hall (Madras) has been transferred by the Secretary of State for India to temporary half-pay subject to Her Majesty's approval.

NAVAL MEDICAL SERVICE.

The following appointments are notified: — Surgeons: E. E. Kershaw to Malta Hospital and R. H. Way to the *Howe*.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Major Thomas William Richardson, late Norwich Company Volunteer Medical Staff Corps, to be Surgeon-Captain.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Cameronians (Scottish Rifles): James Livingstone Loudon, M.B., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Lieutenant-Colonel J. Clark, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement.

THE MATABELE RISING.

The news from the Cape as to the extent of the Matabele rebellion and the perilous position of Bulawayo, the centre of the Chartered Company's possessions, is serious; and, looking to the nature and dimensions of the crisis, a determined effort will have to be made by the authorities in South Africa and in this country if peace and order are to be re-established in that territory. General Sir Frederick Carrington, who has had long experience of African warfare, has been appointed by the Home Government to command the forces in Matabeleland. There has already been a good deal of fighting, and the whole country around is in the hands of the Matabeles; Bulawayo is garrisoned by a small force, is badly provisioned, and not too well supplied with ammunition. There is plenty of excellent material in South Africa, accustomed to savage warfare, out of which a strong local force could be organised, but reinforcements of regular troops will, no doubt, have to be despatched from this country to take part in quelling the rebellion. Orders have been already sent to Aldershot to hold some troops in readiness for embarkation to South Africa, and there is much activity at Woolwich Arsenal in the preparation of supplies of warlike stores and ammunition. The *Spectator* makes a suggestion to philanthropists in regard to the supply of medical aid and material. Our contemporary recommends that half a-dozen picked surgeons should be sent to Bulawayo with antiseptic appliances, and implies that there is a deficiency in this respect, adding that if Bulawayo is really besieged half the wounded may die of infective wound diseases. We do not, of course, know whether our contemporary speaks from any special knowledge of the facts out there, and can only trust that the supply of surgeons with surgical and antiseptic material is ample, as should certainly be the case, to meet the indispensable requirements of modern surgery.

THE ARMY MEDICAL STAFF.

A correspondent who writes most temperately on the present unsatisfactory conditions under which the officers of the Army Medical Staff are now serving, and who draws our attention to the current rumour with regard to the revival of the regimental system and the abolition or reorganisation of the Army Medical Staff, suggests that the following lines should be followed by the authorities when the question again comes to a head. They are, he says, the expression of the feeling of a large body of the best medical officers now serving in Her Majesty's Army. The suggestions are as follows: 1. The establishment of a royal corps of surgeons to be called the corps of "Royal Surgeons" and to be recognised by the letters "R.S." after the titles of the different ranks. The corps to consist of the officers of the Army Medical Staff and the non-commissioned officers and men of the Medical Staff Corps. 2. The amalgamation of the Army Medical Staff and the military division of the Indian Medical Service. 3. If thought necessary the attaching of young officers of the Royal Surgeons to regiments for definite periods. Our correspondent reminds us that the Royal Engineers were years ago in much the same unhappy state as the officers of the Army Medical Staff are at present, and that the honourable position now accorded to the officers of the former service is chiefly owing to the formation of their Royal Corps.

THE NILE CAMPAIGN.

There is but little to chronicle this week in regard to the progress of the Nile Expedition and the late attack at Suakin. It appears that some friendly Arab tribes have recently made a demonstration on the Nile beyond Dongola in the Monasir district, and that this, combined with the defeat of Osman Digna in the Suakin district, has somewhat disconcerted the Dervish leaders. The Dervishes are stated to patrol the neighbourhood of Akasheh every night, and it is alleged that Osman Digna is at Harasab, and that he is receiving large reinforcements, but that the adequate provisioning of his army is a source of difficulty. Great activity still prevails in the transport department of the expedition at Wady Halfa and elsewhere, and in planning and arranging the hospitals and transport for the sick and wounded. Bearer companies will be stationed at Sarras, Ambigole, and Akasheh. It is understood that a considerable force from this country will, later in the season, proceed to Egypt to take part in the Anglo-Egyptain campaign up the Nile. It is currently reported in Cairo that Sir Redvers Buller will arrive there in August in connection with the Dongola expedition.

THE GOVERNMENT OF INDIA AND THE HEALTH OF THE TROOPS.

A severe epidemic of enteric fever is reported to have broken out in the Norfolk Regiment stationed at Allahabad. Since March 1st 20 deaths have occurred out of 47 cases. The *Times* says:—"An important step is about to be undertaken by the Government of India with the view of reducing the amount of sickness from cholera, enteric fever, &c. A special sanitary officer of proved bacteriological knowledge is being appointed to each large cantonment. These officers will be charged with the care of the general health of the troops, so far as it is possible to secure this by careful sanitary precautions. Their duties will include the conducting of full inquiry into the causes of outbreak of all epidemic diseases."

THE RUSSIAN RED CROSS EXPEDITION.

The Red Cross expedition to Abyssinia is under the command of General Shoedoff, and comprises some thirty medical men and nurses, with fifty assistants. Some difficulty has arisen, as we have already intimated, with the Italian Government in connexion with this mission to the Abyssinian forces, and it is understood that the expedition will not be allowed to proceed *viâ* Massowah. From whatever cause this has arisen—and we can only suppose that it has occurred from some doubts being entertained on the part of the Italians as to the purely philanthropic nature of the expedition—it is, on the score of humanity, to be regretted.

HEALTH OF CALCUTTA.

Dr. W. J. Simpson in his report on the health of Calcutta for December, 1895, states that there were 80 deaths from

Digitized by Google

cholera against 144 in the previous month. The figure is lower than all of the corresponding figures of the past ten years, excepting 1892, 1893, and 1894, and is lower than the average of the decade by 41.

BUBONIC PLAGUE AT HONG-KONG.

The outbreak of plague in this colony still continues. Mr. Chamberlain has received telegraphic intelligence from the Governor of Hong-Kong that sixty-four further cases occurred in the week ending the 21st instant.

Surgeon-Major-General William R. Rice, M.D., C.S.I., Bengal Retired List, has been made Honorary Physician to the Queen, vice Inspector-General Sir W. MacKenzie, K.C.B., C.S.I., Retired List, deceased.

The post of Professional Assistant at Headquarters, which will become vacant on the appointment of Surgeon-Major-General Jameson to the office of Director-General, has been conferred upon Surgeon-Major-General W. Taylor.

"Audi alteram partem."

THE REGISTRATION OF MIDWIVES.

To the Editors of THE LANCET.

SIRS,—The writer of the very interesting and able article on Midwives Bills in THE LANCET of April 18th has fallen into one very curious error, to which, I am sure, he will forgive me for calling attention. He says: "The General Medical Council suggested the substitution of the title of 'Midwifery Nurse' for that of 'Midwife.'" By a reference to your report of its proceedings[1] it will be seen that, so far from this being the case, the General Medical Council, after fully considering the suggestion to that effect, rejected it. The error, no doubt, arose from the circumstance that the title of the Bill as sent up by the General Medical Council to the Privy Council contained the words "midwifery nurse," although by special resolution it had been decided not to recommend the introduction of these words into the clauses of the Bill itself.

In respect to the suggestions of the General Medical Council having been ignored in the present Bill the writer says that their omission throws on its promotors a great responsibility. So it would if the omission were the act of the promoters, but it is not. It was the Privy Council that rejected these suggestions. The rejection embraced the entire series with one single exception, and that exception was made at the instance of the promoters. The alterations made in the Bill during its progress in the House of Lords were all made by the Privy Council. In one or two instances the alterations were undoubted improvements, but the majority of the alterations were, in the opinion of the promoters, the very reverse of improvements. As an example may be mentioned the omission of the clauses that provided for the efficient control of the practice of midwives. The promoters are quite prepared to support the reinstatement of these clauses. With regard to the suggestions of the General Medical Council your article specities one or two that, in the opinion of the writer, ought to have been adopted, particularly the suggestion that before existing midwives be allowed to register evidence should be produced as to their character and capacity. It must not be forgotten that on this very question of requiring evidence of moral character a former measure was wrecked. The Bill was "talked out" by the late Mr. Bradlaugh, on the ground that it was monstrous to demand evidence of moral character in the case of midwives seeking to be registered when it was not demanded under similar circumstances in the case of medical practitioners. The promoters of the Bill have, indeed, encountered great difficulties in connexion with this part of the question. They consider it very reasonable to ask that existing midwives should be required to produce evidence of being respectable and competent before being admitted to the Register. But they are told that they must be satisfied with the fact that registration can be refused to any woman who has been shown to be guilty of acts which, if they had been proved against her after being placed on the Register, would have afforded sufficient grounds for her removal from it. The Dentists' Register and other registers are, much against the will of their promoters, burdened with the names of undesirable and incompetent persons. It was found impracticable to avoid it then, just as it is now. To most of the points which the writer of the article mentions as desirable the promoters of the present Bill have not the slightest objection.

Will you allow me, as one possessing some claim to a special acquaintance with the subject, to make a few observations on the other Bills you mention? The adoption of the term "midwifery nurse" has been stated by Sir Walter Foster, M.P.,[2] to be the preliminary to placing the midwife under the direct superintendence of a medical practitioner, and the term was avowedly coined with this intention. Both the Bill drafted by the Parliamentary Bills Committee of the British Medical Association and that drafted by the Lancashire and Cheshire branch of the same association adopt the term "midwifery nurse," presumably with the object above mentioned. Now, in the report which prefaces the latter there is the following remarkable statement: "Your committee have fully considered the question of the attendance on cases of midwifery by persons other than registered medical practitioners, and are unanimously of opinion that the proposition that it be made compulsory for every woman to have a registered medical practitioner in attendance at confinemant, or that no persen other than a registered medical practitioner, or a person acting under the direct or personal supervision of such, be allowed to attend any case of midwifery is, however desirable, impracticable." The object for which the term was coined is, therefore, stated by its originators to be unobtainable. Further, it has been overlooked by the promoters of these two Bills that if the term "nurse" be applied legally to a class of women who attend cases on their own account it at once establishes a "nurse" as a person who may be in attendance without a medical man—namely, as, in a very real sense, a "new class of practitioner." The promoters of these two Bills distinctly state that they do not expect every case of confinement attended by a "midwifery nurse" to be attended by a medical man too. They acknowledge that the "midwifery nurse" must act without the direct supervision of a medical practitioner—that is, as a midwife—yet without any solid reason they want to exchange for the well-known and well-understood term of "midwife" a term which no one knows and which does not mean what its constituent words would seem to imply.

Sir Walter Foster, M.P., states that he would have no objection to the Bill now before the House of Commons if the change of term were made. He agrees with the promoters of the Bill that the present state of affairs in regard to attendance in childbirth amongst the poorer classes is scandalous and cannot be allowed to continue. Yet he, with others, insists upon an alteration which, if adopted, would be useless in regard to the attainment of its avowed object, and which is interpreted outside the profession as the expression of a desire on the part of the medical profession to have all the midwifery of the country in its own hands. I have had ample opportunity of studying the attitude of the non-medical public towards this question, and I can testify that there is a steadily increasing impression abroad that the medical profession, in these various Bills for the registration of midwifery nurses, is trying to get into its own hands that large proportion of the midwifery practice of the country (amounting to some half-million of cases per annum) now in the hands of the midwives. It is absolutely necessary that the public should be disabused of this erroneous idea, or it will, I am assured, bear very disagreeable fruit in the not far distant future, when it will take the shape of opposition to medical interests in any future sanitary or other Bill affecting medical practice or in the promotion of our interests. The only way in which this impression can be effectually removed is by united action in the profession itself in support of the general principal of legislation. Let us agree to let the present Bill pass its second reading, reserving our differences for adjustment in the committee stage. Medical interests will be much more likely to receive proper consideration. Do not let us cut our own throats by stickling for meaningless alterations of title, or, still worse, for the insertion of clauses that, however desirable from a

[1] THE LANCET, June 8th, 1895, p. 1474.

[2] THE LANCET, June 8th, 1895, p. 1474.

Digitized by Google

medical point of view, can be shown to threaten an interference with that very liberty of the subject which it is one of the main functions of the House of Commons to protect.—Apologising for the length of my communication,

I am, Sirs, yours faithfully,

ROWLAND HUMPHREYS, L.R.C.P. Lond., &c.

Fellows-road, N.W., April 18th, 1896.

GASTRO-ENTEROSTOMY: TWO INTERESTING CASES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET for Jan. 20th, 1894, at p. 148, is reported a case of gastro-enterostomy which occurred in the Peterborough Infirmary. The writer of the introductory remarks, alluding to the risk of contraction of the opening after this operation, says: "What the result of suturing the edges of the opening in the manner adopted by Dr. Walker may prove remains to be seen. It is important that the result should be recorded." I now give the result. The patient was operated upon on May 18th, 1893; she died on May 20th, 1895; in the interval she looked after her family and assisted to maintain them by going out washing, &c.; she remained perfectly free from symptoms of obstruction to the passage of food from the stomach, dying from the effects of secondary growths which formed in the lower part of the abdomen and elsewhere. I adopted the same method in a case in which I operated on Sept. 3rd, 1894. The patient made an excellent recovery, dying on Oct. 30th, 1895, with secondary deposits in the liver and elsewhere, having been free from sickness and able to eat solid food without discomfort from the time of the operation. Post mortem the artificial opening between the bowel and the stomach was found quite patulous, admitting my forefinger up to the second joint. The specimen is now in the Pathological Museum of Cambridge. The perfect result in these two cases must, I think, be partly, at least, due to the method of suturing the margins of the openings before approximating them, described in the report of the first case in your columns. I am, Sirs, yours obediently,

THOMAS JAMES WALKER.

Westgate, Peterborough, April 21st, 1896.

*** We are indebted to Dr. Walker for this important addition to the notes of the case which was published in the Mirror of Hospital Practice. Our records are much increased in value by such contributions. That they are required is proved by the hesitancy which some physicians still have in recommending this operation at the right stage even in suitable cases. We congratulate Dr. Walker on the success of his operations. The method of suturing in these cases was as follows. The peritoneal and mucous edges of the opening in the stomach were stitched together with the idea of preventing contraction. The jejunum was opened and the edges were treated in the same way. Senn's plates were introduced, but before drawing the silk tight the peritoneum of the stomach and that of the jejunum near the posterior edges of the plates were united with silk, thus forming a semicircle of stitches guarding the opening posteriorly; the plates were then drawn tightly together, and an anterior semicircle of stitches was then inserted, thus completing the circle of guarding stitches.—ED. L.

"THE EFFECT OF MUSCULAR WORK UPON THE ALKALINITY OF THE BLOOD."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 11th Mr. W. B. Fotheringham has pointed out a contradiction which exists between the views of Dr. Haig on the above subject and those which were expressed by myself in an article published in THE LANCET of March 7th of this year. Mr. Fotheringham rightly insists that the credibility of Dr. Haig's theory of the cause of fatigue stands or falls with the correctness of his view as to the effect of muscular work upon the alkalinity of the blood. According to Dr. Haig the effect of such work is to increase the alkalinity of the blood. In my article the diametrically opposite statement was made. The evidence for the truth of that statement I did not give in detail, but as Mr. Fotheringham has raised the question as to what is really the effect of muscular work upon the alkalinity of the blood it is only right that I should furnish some proofs of the correctness of my statement. The subject has been investigated by Geppert and Zuntz[1] in rabbits. They found a reduction of alkalinity in the proportion of 106 to 248, or to more than one half the normal. Drouin, in the thesis to which I referred, obtained a similar result in rabbits. Pelper,[2] employing the titration method, confirmed these observations in the case of the human subject, the reduction he found being in the proportion of 182 to 218. The most recent and complete investigation of the subject, however, will be found in the article of Cohnstein.[3] He has clearly shown that the effect of muscular work is always to reduce the alkalinity of the blood. In vegetable feeders, for reasons which I have not space to discuss here, this reduction is more marked and lasts longer than in animal feeders, but even in the latter it can always be observed. I further stated that lactic acid was probably responsible for the reduced alkalinity. The evidence for this statement is that lactic acid is always found to be increased in amount in the blood after muscular exercise. Experimental proof of this will be found in the papers of Spiro[4] and of Werther.[5] In the light of the above evidence I think Mr. Fotheringham will agree that I was fully warranted in my assertion that the effect of muscular work is to reduce the alkalinity of the blood. I had at one time intended to refer to the relationship of some facts in the chemistry of the blood to the theories advanced by Dr. Haig, but I refrained from doing so in order to avoid controversy. I would only point out here with reference to the point under discussion: (1) that normal sweat is not acid and therefore cannot be regarded as a channel by which acid in the blood is eliminated; and (2) that it is possible that the immediate fall in the excretion of urea which Dr. Haig has shown to follow exercise is to be explained, in part at least, by the elimination of some of the nitrogen which should appear as urea in the form of compounds of ammonia, these ammonia compounds being required to neutralise the acids produced by the excessive muscular metabolism.

In conclusion, I would only say that no one is more sensible than myself of the value and importance of Dr. Haig's contributions to our knowledge of the physiology and pathology of uric acid, but at the same time I cannot help thinking that he is in error in regarding muscular work as tending to produce an increase in the alkalinity of the blood.

I am, Sirs, yours faithfully,

ROBT. HUTCHISON, M.B. Edin.

THE BRONCHITIS KETTLE.

To the Editors of THE LANCET.

SIRS,—It is akin to presumption to adventure a word of criticism on Dr de Havilland Hall's remarks respecting our old and tried friend, "the kettle," in THE LANCET of April 18th, but surely it is impossible to "practically banish" it from the sick room. The whole of my experience is in its favour in those urgent laryngeal and bronchial cases of very young children, not to speak of the more grave respiratory affections of children of a larger growth, including the dread pneumonias of heads of families, where we are often at our wit's end with a temperature of 103° F. or more, respirations 62, and pulse 120 per minute. On such occasions my advice would be, Exclude the fresh (cold) air and saturate the air of the sick room as speedily as possible and keep it so. "Dry bronchitis" and pneumonias so frequently occur in dry, cold weather as to make the rest exceptional, and to exclude the kettle or its equivalent would be disastrous to the patient. Even chronic catarrhal conditions are frequently benefited by the inhalation of medicated vapour. As to poultices, I have no objection to the exhibition in such cases of an occasional turpentine stupe and a jacket of wadding or other heat retainer, but frequent and good feeding are essential if we are to maintain the patient's strength in the

presence of the increased tissue change accompanying the high fever and hurried respiration.

I am, Sirs, yours faithfully,

April 20th, 1896. ALEX. MCCOOK WEIR, M.D. R.U.I., &c.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Dr. de Havilland Hall's instructive and highly practical article on the Bronchitis Kettle, Poultices, and Over-feeding in Acute Lung Affections, published in THE LANCET of April 18th. Writing on the question of poultices in the pneumonia of infants and young children Dr. Hall says "that the drawbacks inseparable from the use of poultices are not compensated for by the amount of benefit that can reasonably be expected to result from them," condemning especially the heavy linseed poultice. I have frequently seen that old-fashioned and simple contrivance, the hot bran bag, secure all the advantages of a poultice in such cases of pneumonia as alluded to without any of its disadvantages. It retains the heat for many hours if previously heated in the oven, and, being light, imposes no heavy weight upon the little patient's chest. Those of us in general practice have occasionally to respect the time-honoured beliefs of many of our patients, these beliefs in some cases—I do not say in this—having little foundation in fact; and to many of these patients who do not live "in mansions of the blest" the thought of "inflammation of the lungs" brings the thought of the application of heat to the chest inevitably in its train. To ignore this routine treatment in favour of a cotton-wool jacket involves no loss of prestige to "the doctor" if a successful issue result, but if the contrary be the case I imagine he would think it had been at least advisable to combine a line of treatment from which undoubted benefit accrues with a respect for the popular prejudice. Apologising for trespassing at such length,

I am, Sirs, faithfully yours,

C. HAROLD DYER, M.B., C.M. Aberd.

Clarendon-villa, Cleckheaton, Yorks, April 20th, 1896.

"THE NEW INFANTRY SWORD EXERCISE."

To the Editors of THE LANCET.

SIRS,—To an old swordsman cognisant of the fact that the questions at issue between the French and Italian schools have again and again been thrashed out to the *n*th term, THE LANCET of March 28th supplies some curious reading on the subject. Certainly no swordsman educated in the schools of Western Europe would dream of placing himself extended on the lunge in the hopelessly dangerous position depicted by your correspondent. In case of an unsuccessful lunge, if a parry of the ensuing riposte were deceived by a disengagement, anyone in the Italian position would be straight on his adversary's point without the slightest chance of recovery. Mr. Dent well points out that the Italian extension only has to be a little further exaggerated to bring the whole thing to a *reductio ad absurdum*. I know not why this over-extension should be dignified with the title of "Italian method," for in any school, if the fencer be foolish enough to so choose, he may thrust his head forward and over-extend himself. But expert fencers are prepared for this sort of thing and know how to deal with it. In actual warfare—i.e., on rough ground—the probability is that a combatant over-extended on the Italian method would lose his balance and fall over either to one side or the other. As to any previous straightening of the arm on the lunge, however much it may be needful to warn beginners to straighten the arm previously to extension in order to avoid the fatal habit of lunging with bent arm—and to such merely initial practice I presume Mr. Dent alludes—in advanced practice the extension of the arm and advance of the body and lower extremity merge into one combined movement. I can imagine the grim smile that would illumine the countenance of Roman Schweizer—if he were still living—or that of any other great swordsman of the last forty years as he exclaimed, in reference to this wonderful extension: "That is just the position in which I should like to see my adversary so as to knock his head all to little pieces." When the members of the British army have perfected themselves in the Italian practice, by all means let them send another invitation to "Point du Jour," and ascertain whether they can lower the magnificent record of the French fencers exhibited on the occasion of their last visit to Islington.

I am, Sirs, yours very truly,

April 20th, 1896. GEORGE BARRACLOUGH, M.R.C.S. Eng.

"THE QUESTION OF MEDICAL DEFENCE."

To the Editors of THE LANCET.

SIRS,—Your correspondent, Dr. L. Drage, advocates the absorption of the Medical Defence Union by the British Medical Association solely on the ground of economy. If the Medical Defence Union were living up to or exceeding their receipts this might be a reasonable plea, but when the financial statement contained in the annual report shows there was a balance left for the year of £316, which, added to the balance of £325 remaining from the previous year, makes a total of £641 in hand, this cry for economy is manifestly a false one. The main object of his letter is to endeavour to make the British Medical Association a gigantic trades-union for the medical profession by compelling every medical man to join the Association, and then will come the tyranny of the few over the many. I admit there may be occasions when medical men ought to join together and stand firm for their just rights, as they are doing at Cork, Lincoln, Portsmouth, and other places, but they know well what they are fighting for and are continually in counsel together. But to propose that the whole medical profession are to be ruled by the clique that forms the Council of the British Medical Association is most objectionable. The Medical Defence Union is doing its work well and to the satisfaction of the members. As I said at the annual meeting, why not leave well alone? The president, secretaries, and the solicitors seem to thoroughly understand the special work required of them, and surely a subscription of 10*s.* a year is little enough to pay to insure yourself from false charges and the worries of a lawsuit. Mr. Felce stated that the name of the Medical Defence Union was sufficient to stay an action very often, and, if so, why alter it? I heartily thank you, Sirs, for the able articles in which you have opposed the absorption of the Medical Defence Union into the British Medical Association, and I believe this is the general opinion of the members. Let the last annual report of the Medical Defence Union be well circulated among all members of the profession and many more will be glad to join such a successful union.

I am, Sirs, yours faithfully,

Highbury, April 20th, 1896. GEORGE T. KEELE.

MICROSCOPICAL EXAMINATION OF PLACENTAL TISSUE.

To the Editors of THE LANCET.

SIRS,—I remember a case which impressed me somewhat at the time it occurred and which may interest some of the readers of THE LANCET.

When I was attending the lectures on midwifery at St. George's Hospital my father directed me to ask the curator of the museum to examine the substance which passed from the bowels in the case of a woman who had married about two years before. Instead of being confined as was expected at the usual time nothing occurred, but she remained with all the symptoms and signs of pregnancy. After several months this material from the bowels began to escape, but the question whether it was or was not placenta was not decided by our curator, good microscopist though he was.

The end of the case was that one night my father bade me be ready early before lecture to call in Park-lane and make a post-mortem examination. I did this and found a fully developed infant in the abdominal cavity and the remains of a placenta adhering to the intestine. It was clear that the substance which had been passed before death was placental tissue. I am afraid that the microscopical examination of placental tissue at almost all stages is not as conclusive as one would wish or can claim for it.—I am, Sirs, yours, truly,

West Kensington, April 14th, 1896. ROBERT LEE.

VENTRO-FIXATION.

To the Editors of THE LANCET.

SIRS,—*Apropos* of your report of the discussion on Ventro-fixation at the British Gynæcological Society on the 9th inst.

Digitized by Google

one is very much struck with the great diversity of opinion as to the result and consequent advisability or otherwise of performing the operation. It appears to me that the great cause of this disparity of results is due in a large measure to the fact that most, if not all, of the operators speak of retroflexion and retroversion as one and the same disease requiring the same treatment. It is easy enough to understand that if one hangs up to the abdominal wall a retroverted uterus a practical cure may be expected; but very different indeed is the case with a retroflexed uterus, for here one has a flexion as well as a prolapse to overcome; therefore, it follows that relief is afforded so long, and so long only, as the tension between the fixation point on the abdominal wall and the attachment of the posterior wall of the vagina about the sphincter vaginæ is sufficient to straighten the flexion; hence it is that failure follows some operations from the first and others at various periods. It would be interesting to know the proportion of failures from operations undertaken for retroversion as compared with those undertaken for retroflexion.

I am, Sirs, yours faithfully,

Peckham, April 19th, 1896. ROBERT HUGH HODGSON.

1828—A PALEOLITHIC FRAGMENT.

To the Editors of THE LANCET.

SIRS,—In Chapter XV. of the very interesting Biography of the Founder of THE LANCET, published in your issue of April 11th, the causes which led to the action for libel brought by Mr. Bransby Cooper, Sir Astley Cooper's nephew, against Mr. Wakley are reviewed. After the operation of lithotomy performed by Mr. Cooper had ended so disastrously the following epigram, which may amuse some of your readers, went the round of medical circles in the metropolis:

"When Astley's 'nevvy' cut for stone
His toils were long and heavy,
The patient quicker parts has shown—
He soon cut Astley's 'nevvy.'"

The verses, perhaps, fall into the category of neither good nor bad (the "sunt quædam mediocria" of Martial), but they appear to have been greatly relished in 1828.

I am, Sirs, yours faithfully,

April 20th, 1896. W. W. J.

"PUBLIC HEALTH APPOINTMENTS AND THE 'LOCAL' CANDIDATE."

To the Editors of THE LANCET.

SIRS,—As a medical officer of health of ten years' standing and an applicant for public health appointments in various parts of the country I can corroborate every word written by "Semper Vigilans" in THE LANCET of April 18th. I had some time since written a somewhat similar letter to his to draw the attention of the profession to this injustice to a large number of well-qualified members of the public health service. When a vacancy is advertised in the medical papers everyone naturally concludes that it is a *bonâ-fide* vacancy. Many men, misled by the appearance of genuineness, go to the expense of having testimonials printed and sending these and copies of their applications to a large number of members of town or district councils. These men are not aware that in 999 cases out of 1000 the post is virtually filled up before the advertisement appears and that the advertisement is put in the papers simply to comply with a by-law of the council which directs that the post shall be advertised vacant. A man's qualifications for the post, no matter how good they may be, are as nothing compared with a little local influence. Through these spurious advertisements men are dragged sometimes from long distances to some of the most outlandish places simply to be made fools of. Then, again, the advertisements frequently state that canvassing will disqualify, but this applies only after the advertisement appears and after the local man has been all round and secured his votes. In many cases, too, even after the appearance of the advertisement the local man goes on quietly with his canvass. The councillors wink at this, but let an outsider attempt the same thing and their righteous indignation (!) bursts forth in an instant and knows no bounds. To prove what I say I will give only one example from among many that I know of personally. This example is by no means an isolated one, for such things are of almost daily occurrence.

An advertisement appeared in the medical papers last autumn for a medical officer of health to the rural district council of ——shire. Eleven men applied from all parts of the country, with, of course, the inevitable "local" man. *There was no selection of candidates.*

Candidates were told in the advertisement to attend and ten of us did. The outsiders were men with good public-health qualifications—D.P.H., B.Sc., &c.—and their experience of medical officer of health work extended from one to ten years. The local man was almost unanimously appointed. Now this I consider a gross injustice to the ten outsiders, who were trusting to their qualifications for the post and were expecting to be judged on their merits. The payment of third-class railway fare does not compensate a man for the loss of a day's work, much less for the annoyance of being fooled. Then, again, it is an injustice to the ratepayers of the district. The cost to the ratepayers of the rural district named in this case was about £10, a totally unnecessary and unwarrantable expense to them. In my opinion it would be far more honest either to not advertise at all or to add a postscript to the advertisement stating that there is a local candidate in the field. Surely one has a right to ask for common-sense and justice to be exercised in all cases of this kind. This injustice and many others to which we have at present to submit are potent reasons why the supervision of the nation's health should be in the hands of men who are State appointed instead of being in the hands of men appointed by any little local body who have failed to grasp the importance of the duties they have undertaken to perform. Trusting that this matter will be thoroughly discussed, I am, Sirs, yours faithfully,

April 21st, 1896. DECENNIUM.

VACCINATION: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—As small-pox now appears to be so prevalent in many districts, and so many people evade the law, I think if boards of guardians, instead of appointing a public vaccinator for a district, would allow parents to take their children to the medical man of their choice, the board to pay for each successful vaccination the sum of 2*s*., there would not be any excuse for parents failing to fulfil the vaccination laws. I always vaccinate free all children whose births I attend and never now find any opposition from the parents.

Yours faithfully,

April 21st, 1896. VACCINATOR.

THE BATTLE OF THE CLUBS.—XXVIII.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1026.)

WALSALL:—FORMATION OF A MEDICAL UNION.—THE MEDICAL PROFESSION AND THE FRIENDLY SOCIETIES.—TRADE AND MEDICINE.—THE FAMILY CLUBS.—WOMEN'S PUBLIC-HOUSE CLUBS.

THE Battle of the Clubs is no new cry in Walsall. It is a subject which has attracted the attention of the public and the profession for many years. There have been any amount of disputes, public meetings, discussions, controversies

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Aug. 24th, 1895, Brussels; (2) Aug. 31st, 1895, Brussels; (3) Sept. 21st, 1895, Portsmouth; (4) Sept. 28th, 1895, Portsmouth; (5) Oct. 5th, 1895, Eastbourne; (6) Oct. 12th, 1895, Lincoln; (7) Oct. 26th, 1895, Lincoln; (8) Nov. 2nd, 1895, Grimsby; (9) Nov. 9th, 1895, Bexhill-on-Sea; (10) Nov. 16th, 1895, Hull; (11) Nov. 23rd, 1895, Hull; (12) Dec. 7th, 1895, York; (13) Dec. 14th, 1895, Northampton; (14) Dec. 21st, 1895, Fermanagh Medico-Ethical Association; (15) Dec. 28th, 1895, Northampton; (16) Jan. 4th, 1896, Birmingham; (17) Jan. 18th, 1896, Birmingham; (18) Jan. 25th, 1896, Club Practices in Rural and Mining Districts; (19) Feb. 1st, 1896, The Formation of a Provident Medical Association at Folkestone; (20) Feb. 8th, 1896, The Manchester Medical Guild and Medical Aid Associations; (21) Feb. 15th, 1896, The Leicester and Leicestershire Provident Dispensary; (22) Feb. 22nd, 1896, The Organisation of the Profession at Leicester; (23) March 7th, 1896, Loughborough: Local Efforts Defeated by Consultants from Neighbouring Towns; (24) March 14th, 1896, Medical Aid Societies in Small Heath; Medical Clubs at Stockport; (25) March 21st, 1896, General Meeting of the Profession and the Formation of a Union at Nottingham; (26) April 4th, 1896, Nottingham; the London and Manchester Industrial Assurance Company, Limited; the Public-house Medical Aid Clubs; United Action at Lincoln; (27) Leicester and Wolverhampton; a Hastings Dispensary wound up.

Digitized by Google

in the press, and even lawsuits on the subject. The principal cause of the quarrel was the formation of the Walsall Amalgamated Friendly Societies' Medical Association, now more than ten years ago. The medical men in the service of the various benefit societies at that time were naturally not a little annoyed to find that the members they were in the habit of attending in their own surgeries would be taken away from them and placed under the care of the stipendiary physicians the association was about to employ. The organisers of the movement, however, persuaded the members of the friendly societies that it would be much better if they had a medical officer who would be exclusively at their service. They said all they could against the old system, so that when the association began its work there was no disguising the fact that it was run to the detriment of the local practitioners. The latter on their side did not fail to show a marked aversion to the newly-formed institution. Not a few members of the friendly societies were pained to find that the medical attendants to whom they had been accustomed all their lives no longer recognised or saluted them. Many members hesitated to join the association; they felt that if it failed they could expect but small mercy from their former medical men if they were forced to return to the old system. Thus the formation of the Friendly Societies' Medical Association set up a state of enmity between a large section of the community and the local practitioners. So marked was this unhappy state of affairs that when it was proposed to establish a similar institution in the neighbouring town of Bloxwich the president of the Walsall association warned the friendly societies of Bloxwich to be very careful and not to proceed further with their scheme unless they were sure of success, as they could not expect much kindness from the local practitioners if, after acting against the interests of the medical profession, they were to fail in establishing their association. As a consequence of these hostile feelings the patients of the Friendly Societies' Medical Association did not care to call into consultation local consultants, and therefore sent to outlying towns for consultants, and this entailed much extra and unnecessary expense. The same argument applied to cases of emergency when the members of the association wished to call in a private practitioner and yet feared to do so. Under these circumstances the association found itself in difficulties. It had not many members, and to increase the number of members it tolerated all manner of abuses. Rich persons were allowed to join, and some laxity was shown with regard to the granting of medical certificates to malingering members. If the medical man, as a matter of conscience, refused such certificates complaints were lodged against him, he was brought up before the committee, and the latter, instead of supporting him in the execution of his duty, inflicted a reprimand. "Anything to oblige" was the policy they enforced on their "paid and humble servant" the medical officer. One of the Foresters' Courts, "Garibaldi," however, complained through the secretary of the court of the excessive amount of sick allowance that had been paid to the members. Another club also protested; members were constantly ill when they wanted a holiday or were out of work. The clubs therefore complained because medical certificates were too easily granted. On the other hand, if the medical officer showed a little independence and refused a certificate when he saw that it was not really required the disappointed member at once sought, and often with success, to form a party which acted against the medical officer, created imaginary grievances and sometimes even obtained his discharge.

In respect to the granting of medical certificates of illness I found at Walsall plenty of evidence that this, though a difficult matter in all practice, is fraught with more than usual perplexity for the unfortunate stipendiary medical servant of a friendly societies' dispensary. If a private practitioner refuses to give a certificate to a patient he may vex and even lose his patient, but nothing worse than this can happen. The club medical officer runs the risk of losing not one but all his patients. Yet if he gives certificates too freely he increases the calls upon the sick fund and thus again exposes himself to blame. His position is far from enviable.

In spite of these obstacles the Walsall Amalgamated Friendly Societies' Medical Association in the course of time managed to make considerable progress. Though this success was undoubtedly in a great measure due to the skill and devotion of the medical officers, these latter were not allowed to share in the profits that accrued. A letter dated Oct. 25th, 1892, appeared in the columns of THE LANCET written by Dr. D. Riordan, who was medical officer to the association when it had only 1800 members. He then received £180 with the promise that the pay should be raised to £200 as soon as the Association proved a success. This was done in the course of a year, but no further advance was ever granted, though the number of members ultimately reached the figure of about 4500. The adults paid 3*s*. 6*d*. per annum, the juveniles 2*s*., and out of this sum the medical officer only received 10¾*d*. It is not surprising that Dr. Riordan gave in his resignation. Dr. Riordan found that he lost much time in attending to chronic cases, or to malingerers, or to persons who came simply for the purpose of obtaining a little instruction and seemed to imagine that because they paid 3*s*. 6*d*. a year, of which the medical officer only received about 10*d*., they had the right to come and question him on scientific or health topics whenever they felt themselves studiously disposed. As a result the medical officer had not sufficient time remaining to attend properly to the serious or genuine cases of illness. Then there was always a tendency on the part of ignorant, inexperienced committee men to become tyrannical. They would take up all complaints and think they were showing their zeal by abusing the medical man. It is true that, in time, the committee realised the error of their ways and made inquiries before they summoned their medical officer to appear before them. As these committee men are, for the most part, workmen who only earn from thirty to forty shillings a week, they look upon the £3 or £4 a week given to their medical officer as a princely income and that no service can be too great in exchange for such a large sum. Yet some of their members are in receipt of much larger incomes. A town councillor for instance, belongs to the Friendly Societies' Medical Association. He pays 3*s*. 6*d*. a year for himself, 3*s*. 6*d*. for his wife, and 2*s*. each for his children. He drives to town in a carriage. He owns house property to considerable value, employs many workmen, and makes a large income. On one occasion he had a dispute with the medical officer of the association, so he took his sick child to see a physician at Birmingham. Then he brought back the prescription and expected the Walsall Association to make up the medicine free of charge.

A great reform would be accomplished if medical aid was given only to the *bonâ fide* full members of the friendly societies. But the canvassers of these societies do not confine their action to the *bonâ fide* members. They include in their canvass the wives of members, the relatives, and perhaps even the mere friends of the real member. All these latter are brought in only for medical benefits. Therefore it is very easy to get on the medical officer's list of a benefit society, for it is not necessary to join the benefit society in any other respect than that of paying the medical aid subscription. Consequently when people find that their medical attendant charges them the ordinary fees they complain, threaten to join a friendly society, and this threat is often realised. The medical aid organisations are spreading all over the country, breaking new ground every day, and, if we note what the effect has been in Walsall, it will not be difficult to realise that, unless the profession are able to resist this movement, medical men will soon be crushed and driven down to a much lower social stratum. The change that has come over Walsall is very marked. The big practices that existed some twenty years ago and were worth from £1000 to £2000 a year have now gone. When the owner of such a practice dies the practice dwindles, it cannot be revived. If a medical man has no private means or a rich wife to help him he can no longer keep up the old social status of the profession.

Apart from the friendly societies, there are any number of insurance companies at work here which organise medical aid. As a result there are entire streets where not a single private patient can be found. These streets are never visited by other than club practitioners. Two-thirds, if not three-quarters, of the population of the town are members of some sort of medical aid society or else become hospital patients when ill. The result is that the great majority of the practitioners at Walsall must have clubs or starve. Now club practice must be a question of quantity, not of quality, and, if club practice is the main source of income, then an immense number of patients must be seen in an incredibly short time. This again must lead to errors of diagnosis,

Digitized by Google

prejudicial to the preservation of public health. In no case is the ability or the qualifications of the medical men who committed these errors subject to any sort of question or doubt. No one is to blame, the blame rests entirely with the system which does not give the medical man sufficient time to examine the patient. A Walsall practitioner informed me that, when doing similar work at Birmingham, he was allowed just one minute to see club patients, and if he exceeded the regulation minute a loud knocking at the surgery door brought the consultation to a close. These are facts on which it is impossible to lay too much stress, for they concern the public at least as much as the profession. They clearly show that if medical men are driven to rely on club practice alone the public will and must suffer. The clubs themselves do not seem to understand that the greater the number of members the worse must be the medical attendance, unless the number of medical officers employed is proportionally increased. At Walsall the Friendly Societies' Medical Association paid their medical officer the same salary when he had to attend to 4000 members as they had given him when there were only 2000 members, and they even refused to allow an increased expenditure for cab fares.

Dr. Riordan was succeeded by Dr. Lynch, who certainly proved one too many for the friendly societies. First he spread terror in their ranks by ordering expensive drugs which they had never heard of before. When the committee complained he appealed to the members, quoted the rule which said they were to have the best medicines, and pointed out that he was obeying their own rules and this in their own benefit. Many members of the society rather approved of this sort of reasoning and when the committee compelled Dr. Lynch to leave some 1800 of the members followed him and established a Walsall Medical Association No. 2. Then the remnants of the old society attacked him for breach of contract because he had pledged himself not to establish a rival practice in the immediate neighbourhood. To this he objected that association No. 2, being composed of members of association No. 1, could not be considered as a rival body. He had as much right to serve the one as the other; both had been his employers. Association No. 2, it is true in the course of time became, practically speaking, a private club in Dr. Lynch's hands; and though he had to pay damages to association No. 1, nevertheless the advantage of independence and of managing his own affairs amply repaid the cost and loss of the lawsuit. This split has taught wisdom to the Walsall Medical Association No. 1. Their present medical officer has not the same grievances as his predecessors. He declared to me that during the two years he had been in their service he had had no complaints to make; he had received no reprimand, and there had been no disputes. His salary had been increased from £168 to £180, and he was under the impression that it would continue increasing as the number of members augmented. Actually there were 2588 members. During the year ending 1895 he had paid 6115 visits and given 13,025 consultations—total, 19,140. For this enormous amount of work he had been paid £168, or on an average a little under 2*d*. per visit or consultation. Even if to this we add the value of house, taxes, gas, &c., provided for the residence of the medical officer, it scarcely brings the average up to more than 2½*d*. per patient seen. Of the 3*s*. 6*d*. paid by adults and the 2*s*. by juveniles as their annual subscription, the medical officer received 1*s*. 1*d*. Of course, when there is such an amount of work for so little pay it is not surprising that complaints should arise of neglect.

Of late years there has been a great increase in Walsall of what are called family clubs. These are to a large extent organised by the collectors of the insurance companies. The collectors of the ——— Company are particularly active in this respect, though the superintendent of the company is altogether opposed to the practice. Nevertheless, most of his agents while collecting the premiums for life insurances persuade the people on whom they call to join the private family club of some private medical man. The general charge is 4*d*. per week for the whole family. The medical man has to give the agent a commission of 25 per cent. and the first four premiums paid. It ominously and often happens that when the family has paid for four or five weeks or so they quarrel with the agent, so that the medical man gets nothing at all. Then the canvasser will set some other agent on to the same family, who in his turn pockets four weeks' premiums; thus the people pay for eight weeks, and during that time the medical officer must attend them if they fall ill though he receives nothing whatsoever for his services. Then, again, the rule is that the family must be in good health when insured, but it is suggested that if there is anybody ill the agent takes them all the same, makes them pay a month's subscription, antedates the receipt, and declares that they had joined before the illness commenced. Thus the agent pockets at once his 1*s*. 4*d*., and the medical man has a sickly family thrown on to his hands which he must attend for 4*d*. per week, minus 25 per cent. or a penny per week commission to the agent. Nevertheless, if this is worked on a commercial basis with the aid of assistants qualified and sometimes not qualified and done in a wholesale manner a comparatively large income can be obtained. Of course it means cheap medicine, scant attendance, and occasional errors of diagnosis, due not to ignorance, incapacity, or obscure symptoms, but simply to the excessive hurry of such work. There is one Walsall medical man in particular who has an enormous practice of this description. Some of his colleagues assured me that it was their conviction that he must have in all something like 10,000 club-members on his books. During the influenza epidemic the road in front of his house was blocked with patients and their friends trying to gain admittance into his surgery. On calling upon this gentleman I found that he had little or nothing to complain about. He maintained that a sort of wage limit, so far as family clubs are concerned, had been established. No family living in a house of a yearly rental exceeding £14 or £15 was accepted. Then he rejected persons suffering from chronic illness and would not attend to accidents or confinements. He further declared that, for the principal clubs, members were examined before they were admitted, and finally maintained that Walsall was "a town of daily bread," so that it was impossible to obtain the usual medical fees from such a population.

There are also in Walsall a number of private individuals who run a variety of businesses with the aid of medical men. For instance, the Walsall Good Samaritan Medical Aid Society, established in 1879, is managed by a Mr. Brookes, who qualifies himself as a "life, fire, plate-glass, and accidental assurance agent." He has no less than six local practitioners in his service and collects 1*d*. per week per member or 4*d*. per family. Another ingenious individual combines the sale of mangles with the providing of medical aid in case of illness. The "Minerva" of Birmingham, which is also a private speculation, employs five medical men at Walsall; in fact, it seems as if the services of medical men are to be used as a bait for any sort of business, but the most scandalous of all are the public-house women's clubs. These are far worse than the slate clubs of Grimsby and the public-house "sick and annuals" of Nottingham. The principal object of several of these clubs is to provide for funerals; a gloomy subject for which drink is a natural antidote. In any case, and for fear doubts should be entertained as to the efficacy of such an antidote, a special rule provides that the members must drink. The printed rule of one public-house club says that the members of the society shall meet at the public-house in question every fortnight, and the members must then "pay sixpence contribution money and three halfpence for ale." Those who are in arrears are to be fined. I was informed that ninety women belonged to this club. They have thus guaranteed the publican a minimum sale of ninety tankards of ale once a fortnight. Those who do not attend have to pay all the same and the beer is served. Therefore those who are present drink not only their own share but the share of the absent members. This naturally leads to a great deal of drunkenness among these women. As one of the objects of these public-house clubs is to provide not only funeral expenses but medical aid, the medical officers attached have a choice supply of alcoholic patients. Considering the rule quoted above, there can be no doubt that they lend themselves to provoke the intemperance which causes the diseases they are subsequently called upon to treat. By these means women are enticed and encouraged to frequent public-houses. Under the pretext of thrift, armed with the plausible excuse of providing for a rainy day, they meet a crowd of boon companions in a public-house and egg each other on to drink.

Mr. Willmore invited all the members of the profession to meet so that I might relate what had been done in other towns and so that some effort might be made to form a medical union. Twenty-five invitations were issued and

Digitized by Google

sixteen local practitioners were able to attend. Mr. Willmore opened the proceedings by explaining that this was but a preliminary meeting convoked for the purpose of seeing whether any sort of action was possible. Even if for the moment nothing very startling could be done, still it would be a good thing if the members of the profession could arrange to meet each other on certain days. This would help "to rub off the corners" and lessen much of the animosity and asperity which were so detrimental to the interests of the profession. At the new hospital, which would be completed in the month of May, there was a board-room where, if a medical society was formed, meetings could be held. There were many grievances to be dealt with. Clubs might be necessary, but touting was not necessary. Then there were the herbalists who had not the qualifications of dispensing chemists and yet they gave consultations, prescribed, and made large incomes out of the practice of medicine. Druggists were also very prone to prescribe, but if such abuses were to be abolished there must be cohesion among the members of the profession. Mr. Willmore then called upon me to address the meeting. After giving what information I could crowd into a short speech dealing with the grievances that prevailed and the remedies that had been attempted, I insisted on the necessity of forming at once a medical union to deal with ethical and economical questions. Some amusing though somewhat despondent speeches followed. One speaker thought union was impossible because ethics in Walsall were an unknown quantity and nothing could be worse than the actual condition of the personal relations between the local practitioners. The general tone of the speeches clearly showed how low the profession had fallen. There was a general cry of "stinking fish." One speaker complained that touting had been set up and organised by medical men who employed insurance canvassers and outbade each other by offering larger and yet larger commissions so as to secure the services of the best canvassers. Competition had become an excuse for every iniquity and it had stamped out all sense of medical etiquette. One practitioner explained how, on arriving at Walsall, he had stoutly refused to have anything to do with the clubs; then, finally, he took people at 10*s.* a year. The result was that about three persons joined his private club, but, as during the first three or four months they did not happen to fall ill, they concluded that they were paying too dearly, so they left him and went to an institution where the subscription was not more than 3*s.* 6*d.* a year. At last he found that he must do what all the other medical men did and take what clubs he could get at the terms currently paid. Nor would it be easy to ask the local practitioners to give up clubs that brought them in £100 or £200 merely on a question of principle. Whatever clubs one medical man might throw over other practitioners would gladly take up. Yet everyone acknowledged that club work was ruining private practice.

From all this it would seem as if the cause of unionism has but poor prospects of success at Walsall. This is not the case. The medical men who attended the meeting were suffering from angry feelings too long pent up. Having now at last had their say they felt wonderfully better. No prescription ever effected a more rapid cure. Practitioners who had not so much as bowed to each other for two years were now found cordially shaking hands, and after some little hesitation and some desultory conversation, with one abstention and no hostile vote, a resolution was carried that a committee of six members should be elected then and there for the purpose of taking the initiatory steps necessary for the formation of a medical union to deal with ethical and economical questions. The meeting also unanimously adopted a resolution expressing its thanks to THE LANCET for the service rendered in raising the whole question. The committee was elected by ballot and then the meeting adjourned. In subsequent conversations I found that some of the speakers who at first deprecated the idea of forming a union had become quite enthusiastic in the cause. It was pointed out that three of the medical men who had not attended were partners and therefore constituted but one firm, and their position was such that even if they did not join the union they would not act against it. Others were the salaried officers of friendly societies and scarcely free to act, so that the number who actually attended and voted for the formation of the union was much larger than could reasonably have been expected for a first effort. The chances of success were, therefore, greater than had been anticipated, and it would be strange if with so fair a beginning good results did not accrue.

THE ASHANTI EXPEDITION.

(BY OUR SPECIAL WAR CORRESPONDENT.)

III.[1]

The Water-Supply of the Troops.

VARIOUS, indeed, have been the causes adduced for the production of malarial or coast remittent fever. For instance, some have suggested "planetary influence," others "want of elasticity in the air"; not a few have thought "withdrawal of elasticity from the human body" had something to do with it, whilst the majority believe the disease has its origin in decomposed organic animal and vegetable matter and general impurity of the water, the last of these coming in for the lion's share of professional suspicion. It was at one time thought that sulphuretted hydrogen gave rise to the complaint, even so celebrated a traveller as Humboldt to a certain extent favouring this idea; but various expeditions sent to the west coast of Africa since his time have in no way helped to solve the problem or done anything to satisfy us on the point in dispute. The ablest scientific researches, carefully conducted by medical officers sent out for the purpose of recording their observations, have one and all rather disproved than otherwise the accuracy of any single suggestion. Whatever may be believed about the admixture of salt and fresh water being capable of producing a special form of fever at the deltas of rivers, the same cause ceases to operate at any distance from the coast or at places away from the direct influence of the sea, such as at Ashantiland, where remittent fever of a virulent character exists probably in an endemic form the whole year round.

Recognising, however, the very great importance attached to a proper supply of good wholesome water for the use of our troops engaged on an expedition such as that to Kumasi, I took care to make a careful chemical examination of nearly all the sources—from Cape Coast Castle to Kumasi—from which a supply had been obtained, and with only two exceptions did I discover *en route* any positively bad water or see the fluid in such an impure condition that it could not, after boiling or filtering, have been partaken of by the men with impunity. Of the two places referred to where the water was qute unfit for use even after precautions had been adopted, one was at Yacumba on this side, and the other at Akusirem, on the further side, of the Prah. Moreover, I thought it best to corroborate my qualitative examinations by sending some specimen water carefully obtained from a river at the rest camp called Mansu to England, so that it might be subjected to a qualitative and quantitative analysis in THE LANCET Laboratory. This said sample, a very fair all-round specimen of what was drunk by the troops out there, has turned out to be quite usable after boiling, for, as the report from THE LANCET Laboratory says: "The water submitted for examination contained a marked amount of organic matter held in solution, yet it was less open to objection because there was no indication that these matters were of animal origin or derived from animal excreta. It was slightly turbid, containing a deposit which, on microscopical examination, proved to consist of vegetable débris. The sample only measured 10 oz., so that it was not possible to make a very exhaustive analysis. On withdrawing the cork a distinct smell of sulphuretted hydrogen was evident, proved by the blackening of a slip of lead paper introduced therein. The presence of this sulphuretted hydrogen, however, could easily be attributed to a reduction of sulphates during transit in a closed bottle by the vegetable matters held in solution, for the water in its original state does not appear to contain any trace of this gas whatever. The total amount of solid matter amounted to 11·9 grains per gallon. On ignition charring occurred and a smell was evolved of vegetable but not of animal matter burning. The reaction for phosphates in the residue was hardly perceptible. There

[1] Nos. 1 and 2 were published in THE LANCET of April 4th and 11th, 1896, respectively.

Digitized by Google

was an entire absence of chlorides. The free ammonia amounted to 0·028 grain per gallon and the albuminoid ammonia, which came off very slowly, to 0·042 grain per gallon." The report concludes: "As might be expected in the presence of sulphuretted hydrogen, neither nitrites nor nitrates were to be found." These views correspond with those expressed by myself after examination of the water at the various rest camps, and must go a long way to show that the water-supply has not proved nearly so impure as was expected, and that the bulk of the water after boiling or passage through a filter might be partaken of without fear of unpleasant results.

At Yacumba, the first halting station, only some seven miles distant from Cape Coast Castle, the supply of water had to be brought to our camp from a sluggish stream some two miles distant from our camping ground. Its colour was of a reddish brown. Moreover, it was quite devoid of transparency and possessed a disagreeable fœtid odour. The rivulet ran through a sort of glen, and its bed was probably some thirty or forty feet below the higher land on which the native huts were erected. Into it several surface drains evidently emptied their contents by a common duct, which could be traced to and communicated with the native township above. Hence the source of native pollution could without difficulty be most easily accounted for. Chemical tests gave positive evidence of its impurity and clearly showed its unsuitability for either drinking or culinary purposes. Major Sinclair, R.E., lost no time in communicating these facts to the headquarters' staff, so as to avoid the use of it by the troops on coming up.

At Akusirem, another rest camp on the other side of the River Prah, matters were even worse. This halting place was selected by one of the colonial authorities, and the camp dwellings were erected by an officer in their employ. Of all the camp sites selected *en route* to Kumasi, this one without a doubt was the very worst selection. To commence with, it was approached and surrounded by a succession of wretched, dismal, offensive-smelling, malarial-reeking swamps. The site was very low, and, to crown all, possessed no proper water-supply whatever. True, on its northern side there existed a sort of mud hole containing a collection of dark-coloured, offensive-smelling fluid which by no stretch of imagination could ever be called usable water, for it consisted simply of drainage percolating through loose sand from an old plantain garden (very possibly a disused native burial ground) above it. To all tests it gave unanswerable results. When seen its impurity was recognised by the principal medical officer, and on his suggestion the desertion of the camp was determined on by the staff as soon as they had arrived on the ground; but this decision was arrived at some time after my own report regarding the character of the water and the other insanitary conditions of the *locale* had been telegraphed back by an officer. Why any delay at all should have occurred in deserting it after the receipt of that telegram by the executive remains yet to be explained, considering that two white officers were then very ill in bed with severe attacks of remittent fever. I am not prepared to say what definite position the civil medical profession held with reference to the military out there; but this I do know, that many of the surgeons in the employ of the colony (in fact, I was told so by them) looked principally for instructions issued by the head of their own department, and scarcely considered themselves in a position or at liberty to act under any other authority. There is a trite saying, "'Between two stools one is apt to come to the ground," and this is particularly applicable to military medical organisation. In the field there should be only one responsible head of the department—the principal medical officer, and his position should be unquestioned and his orders unhesitatingly carried out by the civil as well as the military element acting in concert under him.

Barracou village is situated higher than any of the rest camps this side of the Prah, being some 500 ft. above sea level. Its surroundings are free from objectionable swamps, while the water procured from a running stream near the native village proved excellent on examination. This place was a rest camp during the previous Ashanti War, but was not used as such in the later expedition. Its exclusion from the number of sites chosen probably arose from mileage considerations, the *locale* not dovetailing in with the requisite length of marches decided on. Be that as it may, Barracou is an excellent site for a rest camp and much more suitable from a sanitary point of view than Assin-Yankumasi, which had been selected in its stead, possibly because it is a few miles more distant from the Prah.

At Assin-Yankumasi the water was obtained from a stream, and although not quite so transparent as one could wish, it nevertheless gave negative results with nearly all the tests employed except Nessler's solution, which showed a slight colouring of the fluid when compared with a tube full of distilled water.

During my stay at the Prah River the Pasteur-Chamberland filters, six in number, were brought up. Their arrival was hailed with considerable satisfaction, because it was hoped that the officers and men who had up to that time been forced to drink (previously boiled) river water would now be supplied with a purer and much more wholesome fluid. Being present when their component parts were being put together by the man in charge I had an opportunity of judging of their suitability for the rather rough use incidental to a campaign like that on which we were then engaged, and I must frankly admit that the parts seemed to me to be too numerous and the internal fittings too complicated and likely to get out of order for the rough-and-tumble work to which they were inevitably to be subjected.

To begin with, each of the large galvanised cisterns, supposed to contain many gallons of water, is supported by three long, round, half-inch metal legs. More than one of these bent under the superimposed weight when the tank had been filled with water, or perhaps sank deeper into the earth than its two fellows, and by reason of the list given to the cistern was apt to throw the whole apparatus out of working order. Then, again, there was considerable delay as well as difficulty experienced after getting the bougies into position to secure the lids properly. The rubber bands did not appear to fit in the grooves as neatly as they might be expected to do. Vulcanised material, as everybody knows, perishes or becomes unfit for use very soon after exposure to air in a tropical climate, and its adaptability for the exclusion of air in an apparatus of this kind was not by any means satisfactorily shown as far as I could see. It took some hours before one of these filters could be brought into anything like working order, and when this was accomplished the supply of filtered water fell considerably short of what was expected. After some trials it was found absolutely necessary to do away at once with the useless metal tripods. A more solid foundation for the cisterns in the shape of wooden trestles was supplied. The metal tanks were placed on these supports and relays of natives requisitioned to turn the handles and keep the supply of water up, but in spite of all efforts the result was unsatisfactory, only some forty gallons of filtered water being the result of over six hours' work. Naturally such a result was extremely disappointing. During my stay of some days at the Prah these several filters were more than once taken to pieces—overhauled and carefully cleansed—in order to ascertain if any accumulation of dirt or débris interfered with the working of them, but all to no purpose in effecting any decided improvement in their efficiency, for instead of turning out a sufficient supply of purified water for some 300 or 400 soldiers, as they were expected to do, they failed to afford a third of the amount required for the daily consumption of our men. The result of this failure was that an order had to be issued by the headquarter staff that all the filtered water was to be reserved for the use of the sick, and the healthy had once more to return to the drinking of what was collected by the riverside. Not only were our filters at Prahsu breaking down, but we learnt that at Fosu, where two filters had been left, the authorities were complaining of their inefficiency. "One worked very indifferently and the other not at all." Need I add what a disappointment this proved to us all, who had been led to expect so much from the Pasteur-Chamberland filter? An expert who had been summoned from Cape Coast Castle with a view of setting matters right told me they were larger cisterns than he had been accustomed to. If this be so or not I am unable to say; but all I can vouch for is that they in no way accomplished what was expected of them. The principle (hydraulic pressure) upon which the Pasteur-Chamberland filter is constructed is unquestionably a good one. No one having seen the apparatus in operation can doubt this for a moment. However dirty or discoloured the water may be on introduction, whatever quantity is passed through the filter comes away as bright and clear as possible, every impurity is arrested and may easily be seen and scraped off the surface of the bougies when the lids are removed and the candles are unscrewed for the

A waterfall in a pretty glen near the Monsi Hill, where the water was tested by the Special Correspondent of THE LANCET whilst on the road towards Kumasi. The spring was found situated just abreast of the tent shown pitched near the centre of the illustration. To the left the stream is represented running down to the Kwisa camp, the tops of all the trees in the background being hidden in a dense white fog.

Digitized by Google

purpose of cleaning them. The failure that occurred out in Ashanti was, therefore, one concerning quantity more than quality, and a little more care in their construction may possibly obviate this defect in the future. All use of vulcanised rubber should be avoided, and, if it were possible, automatic rather than manual power should be employed for their operation. In war time, especially during the forward march of troops, it may be rather difficult at times to secure sufficient men to turn the handles of these filters, which manipulation must be provided for if a proper supply of pure and wholesome water has to be kept up. Speaking one day to Surgeon-Colonel Taylor about the unsatisfactory working of the filters that had been supplied for the use of the expedition, he happened to remark that "he had noticed a small narrow stream crossing the road about half a mile out of camp and had seen natives collecting water thereat," and "he wondered whether this was of better quality than that obtained from the river," and "could I trace it up to its source?" Of course I consented, and left him with the determination of searching for the spring of this rivulet as soon as I could. The opportunity for starting on this search presented itself very early the following morning. About 4 A.M. I left camp and came upon the stream in question about three-quarters of a mile on the Barracou road. It was scarcely six inches in breadth. Tracing it in a north-north-east direction for some half a mile or so I found it divided, one branch, the north-east portion, running to the River Prah, while the other coursing but a short distance seemed to be joined by another little rivulet down which water very clear and bright seemed to be coming from a south-south-east direction. I had much difficulty from the immense amount of tangled undergrowth that lined its banks in tracing this stream up to its source, some four hours being occupied in the endeavour, but its spring was at last discovered and I had the satisfaction of bringing back to camp a bottle of the clearest and best water that was ever secured *en route*. Surgeon-Colonel Taylor was delighted with the pure supply that I had through his hint been enabled to discover. From this time no more river water was required during our stay at Prahsu.

Across the Monsi Hill I had another opportunity of testing a spring of really excellent water, which coursed down and supplied the troops at the rest camp of Kwissa (vide illustration).

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester and Salford Sanitary Association.

ON Sunday evening a sermon was preached in the Manchester Cathedral on behalf of the above association by the Rev. C. V. Gorton, Vicar of Morecambe. His subject was "The Laws of Health, the Laws of God." He said that in the Scriptures the word cleanliness was synonymous with holiness, and that the Mosaic priest was really the medical officer of health. The old Greeks, whose aim was the physical perfection of the man, deemed sanitary law a portion of the moral code. He quoted Xenophon as giving one of the best descriptions of the officer of health: "When people are sick, physicians cure them; they are menders of old garments. But your care is to be of another kind: it is for you to prevent the army from becoming sick." (If our military authorities looked at matters more like Xenophon, there would be less cause for discontent in the Army Medical Service.) "It was strange," he said, "that in the early days of the development of Christianity and after the fall of the Roman Empire we looked in vain amongst European peoples for that regard for the law of God. The Church prayed, 'From plague and pestilence, good Lord, deliver us,' but was content to remain unmindful that national judgment was a natural consequence of national negation of the law of God." He reminded his hearers of Lord Palmerston's reply to a deputation requesting the appointment of a day of humiliation and prayer on the outbreak of cholera about the middle of the present century from the neglect of sanitary law: "When man has done his utmost for his own safety then is the time to invoke the blessing of heaven to give effect to his exertions." It was, he said, a good thing that the Manchester Sanitary Association was doing its best to improve all this. "It would be still better if the society were so supported that it could inaugurate branches in every town in the country which would investigate the physical causes of disease, note the rise of epidemics, educate public opinion, and organise the working classes to demand pure air and pure water, and not only a grave to be buried in, but sufficient space in which to properly live." It might have been as well if he had suggested to the "working classes" that when they got their pure air they should not do all they can, as is too much the case at present, to pollute or exclude it from their dwellings.

Our Milk-supply.

Under the auspices of the Milk Dealers' Protection Society of Manchester, Salford, and Surrounding Districts, a lecture was given on April 20th by Mr. W. Cox on Milk as Food in relation to Health. The chair was taken by a member of the city council, who said "the association existed for the purpose of protecting from undue interference a trade in an article that was indispensable to health. It had no sympathy with any milk dealer who violated the rules that were necessary for safeguarding the public health." He considered that the association was right in suggesting that the work of the corporation inspectors should not be confined within the city, but should be extended to the shippons and dairies from which the milk came; and in this we should all agree. Mr. Cox in his lecture did not speak from the standpoint of the man of science, and he would apparently laugh to scorn the patient labours of the bacteriologist, for he is reported as follows: "The idea that the germs of disease were spread by milk he described as 'a craze.'" Save in exceptional cases, in which the germs of scarlet fever or typhoid fever had been directly communicated to the milk by the persons manipulating it, milk had never proved injurious. These are pretty considerable exceptions to start with. He then contended that the facts disproved the idea that the "tubercle bacteria" could be communicated from the affected animal through the milk to the consumer of the milk. May it be inferred from this that Mr. Cox would advise the giving of milk from tuberculous cows to delicate children so long as the poor creatures were able to supply it? "He believed that such infantile diseases as were often attributed to milk were due either to the lack of milk or to the insanitary condition of the houses of the poor; and he said that the healthiness of the children of farmers and dairymen was the best answer to those who said that milk was not healthy." He believed that greater attention should be paid to the periodic inspection of shippons and dairies but apart from that "everything that was necessary was at present one to ensure the purity of our milk-supply." The retail dealers are, of course, immaculate and always take the most scrupulous care to avoid contamination by any even of those "germs" which Mr. Cox holds in such contempt. It is a pity that anyone should discourage the efforts made to secure good quality and purity in a food of such importance as milk, and especially that such discouragement should come from a member of the veterinary profession.

Ancoats Healthy Homes Society.

This society, of which Mr. Aldred is president, gave the last lecture and entertainment for the season on Thursday evening last, when Mr. W. P. Montgomery, assistant surgeon to the Ancoats Hospital, addressed about 800 people on Exercise and Training. The primary object of the society is to give instruction of a useful kind, and this work has been carried on for several years amongst the poorest people of the working-class district of Ancoats; but in order to bring together those who without some such attraction would not attend the additional bait of musical performances, between which the lectures are sandwiched, has been found very successful. The young people in Manchester as elsewhere are open to this influence, and these combined attractions have been successful in securing an average attendance of 650 people at the twenty-nine lectures given during the last session. The lectures and the services of the musical helpers are entirely gratuitous and admission to the entertainment is free. Useful information is given and something done to brighten what to most of us would seem the dull monotony of the daily life of these poor mill hands.

The Manchester and Salford Reformatory.

The fortieth annual report of this institution contains a very important little point. Referring to the falling off in the number of admissions, the report says that if this were due to a diminution of crime it would be a subject for congratulation, but "the governors desire deliberately to place

Digitized by Google

on record their conviction" that it is due to the magistrates committing boys of twelve and over, who have been convicted of crime, to industrial instead of to reformatory schools. The governors think this probably a mistake as regards the boys themselves, and "surely it is a wrong to the other inmates of the industrial school who are not criminals, and some of whom are committed for very different offences, that they should be compelled to associate with convicted thieves." They think the two classes should be kept separate, and earnestly commend this subject to the careful consideration of magistrates and of all interested in the reformation of juvenile criminals.

The Medical Guild.

The quarterly meeting of the Medical Guild was held on April 14th in the Victoria Hotel. The chairman (Alderman Walmsley, J.P.) presided. A discussion took place on midwives registration and afterwards on professional advertising, and the following resolutions, previously passed by the council of the guild, were adopted:—

I.—As regards midwives registration:—

1. That it is the duty of the profession to defend and maintain the Medical Acts.
2. That it is advisable that constructive legislation (defensive is understood) upon the midwives question should be undertaken by the medical profession.
3. That legislation should follow the lines of local registration and sanitary regulations.
4. That the minimum training should be six months' obstetric nursing in a public lying-in hospital or union infirmary, where the pupil shall be present at not less than thirty labours, in every case under the direct supervision of a registered medical practitioner.
5. That no examination should be required and no diploma issued, the sole guarantee of proficiency to act as a midwifery nurse being the certificate from the medical officer of the lying-in hospital or union infirmary, which enables her to be placed upon the local register.

II.—Professional advertising:—

1. While appreciating the legal grounds on which the verdict in Kingsbury *v.* Hart was given, the council expresses confidence in the editor and reference committee of the *British Medical Journal* in their action in the matter referred to in the libel.
2. That this council is of opinion that the evidence having reference to the ethical aspects of the case, Kingsbury *v.* Hart, indicates the distinct necessity which exists for the question of medical ethics being placed upon a firmer basis and dealt with in a manner satisfactory to the profession.

In dissenting from the views expressed by the plaintiff's witnesses in this matter the council suggests the desirability of more stringent and definite rules of medical ethics being authoritatively laid down for the guidance of the profession at large.

April 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University: New Regulations for Graduation in Medicine.

THE Edinburgh University Court at its meeting last week approved the following resolutions regarding the requirements for degrees in medicine under the new ordinances:—A. Every candidate shall be required to attend in addition to present requirements: 1. A course of instruction in mental diseases consisting of not less than six class-room meetings for lectures and demonstrations and ten meetings in the wards of a recognised asylum for the insane. 2. Post-mortem examinations in a recognised hospital for a period of at least three months, during which practical instruction is given in the methods of making post-mortem examinations and in framing reports. 3. A course of clinical instruction in infective fevers given at not less than twelve meetings in the wards of a recognised hospital where clinical instruction is given on cases of infectious diseases. 4. Instruction in diseases of the eye at not less than twelve class-room meetings and twelve meetings for clinical instruction in the wards of a recognised hospital or in a hospital and dispensary, the course to include efficient practical instruction in the methods of examining the eye. 5. A course of operative surgery conducted by the professor or a recognised teacher. B. Every candidate shall also be required to attend any one of the two following courses: 1. Clinical instruction in children's diseases at not less than four lectures and ten meetings for clinical instruction in the wards, together with four meetings in the out-patient department with attendances at post-mortem examinations. 2. Instruction in diseases of the larynx, ear, and nose at not less than six class-room meetings and twelve meetings for clinical instruction. In connexion with the above it was resolved that no fee should be charged for attendance on post-mortem examinations and clinical instruction in fevers; that the fee for operative surgery be £3 3*s.*; for children's diseases, £2 2*s.*; and for mental diseases and diseases of the eye, £2 2*s.* each. The court also received a report by a committee appointed to consider the question o mixed classes in connexion with the medical education o women, and agreed to require that classes shall not be mixed classes except on special cause shown. The court recorded its deep sense of the munificence of the gift of £20,000 left by the Earl of Moray, and determined that it should be called the "Earl of Moray's Endowment."

Milk Prosecutions.

At the Dunfermline Sheriff Court three farmers were convicted of selling milk which on analysis was found to have had from 13 per cent. to 21 per cent. of normal fat abstracted from it, and were fined from £2 10*s.* to £5 for so doing.

Hospital for Infectious Diseases for Berwickshire.

The east district committee of Berwickshire have resolved to erect a hospital for infectious diseases at Ayton. The hospital is to be an iron structure and is to cost about £1000.

Glasgow University.

The formal closing of the winter session took place on the 14th inst., though the classes in the medical faculty ceased at the end of March. The graduation ceremony was presided over by Lord Kelvin, and though the degrees conferred were for the most part in arts, divinity, or law, a few medical graduates were also to be found. The following gentlemen received the degree of M.D.:—W. C. Allardice, M.B., John Donald, M.B., J. C. Robertson, M.B., R. T. Marshall, M.B., the latter being awarded "commendation" for his thesis on "The Mild Malarial Fevers and their Microbes." Mr. D. G. Carmichael was "capped" M.B. and C.M., and the same degrees with "commendation" were conferred on Mr. J. M. W. Morison. After the ceremony the honorary graduates lunched with the Senate, and Professor Gairdner, who presided, proposed the health of Mr. John Ure on whom the degree of LL.D. had just been conferred. Mr. Ure was the chairman of the first health committee in the days when Dr. Gairdner was medical officer of health of the city.

Tuberculosis in Cattle.

A conference of Scottish butchers to consider this subject was held in Glasgow on the 16th inst. The chairman in his opening address contended that butchers were being unfairly dealt with by many local authorities and medical officers of health insomuch as carcases purchased in good faith at the highest market price and in markets under the supervision of the authorities themselves were frequently ordered to be destroyed and yet no compensation was offered. He questioned the necessity for this procedure in cases of well-nourished carcases with a merely localised tuberculosis, but in any case if the interests of the community demanded it the loss should fall upon the public purse. Resolutions defining these views were afterwards passed and were ordered to be sent to the members of the Government.

Microscopical Society, Glasgow.

At the usual monthly meeting of this society on the 16th inst. Dr. T. H. Bryce, lecturer on anatomy, Queen Margaret College, gave a demonstration on "The Development of the Chick," illustrated by lantern slides and microscopic sections.

Medical Appointments.

Dr. John Brownlee has been appointed to take charge under the medical officer of health of the Parliamentary-road Fever Hospital, Glasgow. The vacancy was due to the resignation of Dr. F. Dittmar.—The directors have appointed Dr. A. L. Pentland-Smith to be assistant medical superintendent to the Westgreen Asylum, Dundee.—The Edinburgh parish council last week appointed a resident medical officer to the Craiglockhart Workhouse. Three candidates were nominated for the office including a lady. The result of the first vote was that Miss Lillias Thomson, L.R.C.P. & S. Edin., received nine votes, Mr. George J. Jenkins, M.B., C.M., eight, and Mr. J. J. Hewison, M.A., M.B., C.M., five. The second vote resulted in thirteen votes being given to Dr. Jenkins and nine to Miss Thomson.

Ambulance Inspections.

Favourable repcrts after inspection have been made upon the condition of the ambulance companies of the 3rd Battalion Highland Light Infantry and the 4th (Volunteer) Scottish Rifles. The inspecting officer in each case was Surgeon-Lieutenant Browning, A.M.S.

A Fortunate Village.

Dr. Duncan Love of Cumbernauld, a village with a population of 1000, reports that the village has not had a single case of infectious disease for a period of twelve months.

Casualty Surgeons, Glasgow.

The Police Commission has decided to increase the salary of Dr. Chalmers, casualty surgeon to the Southern District, from £70 to £100 per annum. There is a vacancy in the Western District in consequence of the appointment of Dr. Boyd to be surgeon to the police force.

Aberdeen University.

Twenty-four candidates passed the April medical preliminary examination at the University of Aberdeen.—The University Council has appointed a committee to keep alive an interest in the wants of the university as to new chairs, additional lectureships, and the provision and maintenance of fresh museums and laboratories. Among the "pressing wants" embraced in the recommendations approved of were botanical gardens and residential halls for male and female students.

Hospital Saturday in Aberdeen.

The Aberdeen Town Council has agreed to the request of the committee appointed by the friendly societies by granting the use of Duthie Park on Saturday, June 27th, for a gala. There will be a monster procession through the streets of the city and various sports in the park. The whole proceeds will go to the Royal Infirmary, and given good weather it is expected to raise about £1000.

Corporation Balnearies, Aberdeen Sea Beach—Marine Aquarium.

The new bathing station erected by the town council on the Aberdeen sea-beach, from designs by the city architect and at a cost of between £3000 and £4000, will be opened on May 1st. The building has a frontage of 111 ft., and the external walls are of compressed red brick from Ruabon with white fire-brick facings. The main block, 40 ft. by 35 ft., has open verandahs both on the front facing the Links and that facing the sea, and there is a tower 37 ft. high in each corner, with a water tank in the top of each tower. There is also a central ventilating tower, rising to a height of 44ft. above the ground level. In the basement are the kitchen, laundry, boiler-room, engine-room, pumping apparatus, servants' w.c., &c.; and on the ground floor a large refreshment-room, 35 ft. 9 in. by 17 ft. 6 in., waiting-rooms, the superintendent's room, and the office. Each of the two wings measures 35 ft. by 28 ft. 6 in., and contains eight finely fitted bathrooms, lavatory accommodation, &c. There are four water-supply pipes for each bath—hot sea-water, cold sea-water, hot fresh-water, and cold fresh-water. Behind the old bath-house is an open gymnastic ground fitted with horizontal and parallel bars, vaulting horses, giant strides, &c. In the refreshment room in the former bathing station is to be provided—on the suggestion of Mr. H. Alleyne Nicholson, M.A., M.D. Edin., D.Sc., Professor of Natural History in the University of Aberdeen—a marine aquarium, while in an adjacent room will be a tank for the scientific observation of sea animals during life. The aquarium will be under the scientific direction of Professor Nicholson and assistants. It will be on a small scale at first, the cost being £60, but it is hoped that it will form the nucleus of a valuable marine zoological observatory. All the inside baths, bathing coaches, and bathing arrangements on the sea beach are under the direct management of the municipal corporation.

April 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

AT the last meeting of the Public Health Committee on the 15th inst. Sir Charles Cameron reported that during the first fourteen weeks of the present year the death-rate was 7·3 per 1000 below the mean rate for the corresponding period in the previous ten years. During the week ending April 11th, 1896, there were but 12 deaths from zymotic diseases, while in the corresponding week of last year the number was 23. During that week one case of typhus fever was notified under the provisions of the Infectious Diseases Notification Act. It is now quite an unusual thing for even one case of typhus fever to be notified in Dublin or to be received into the Dublin hospitals, where some twelve years ago typhus fever was almost as common in the wards as typhoid fever. At the annual meeting of the supporters of the Adelaide Hospital, on the 15th inst., the medical report, signed by Dr. James Little and Dr. Wallace Beatty, contained the remark, "It is interesting to note that but seldom now do we see typhus, no case of this formidable disease having been admitted to the hospital for years. The disease has ceased to prevail in Dublin." Now this remark applies to practically all the general and even fever hospitals of Dublin, and it is not alone interesting but very satisfactory to note that a disease which was more than once so widely epidemic as to constitute a plague in Ireland has now become so rare that the occurrence of one case in the person of a woman living at the north side of the city has become a notable circumstance.

Automobiles or Horseless Carriages.

On April 16th, at a meeting of the Belfast Natural History and Philosophical Society, Mr. John Brown (the honorary treasurer) gave a most interesting lecture before a crowded house on horseless carriages. The Lord Mayor presided, and a great many members of the medical profession, to whom these methods of locomotion may eventually be of the utmost value, were present. Mr. Brown has for some time given great attention to this subject and during a recent visit to France purchased an automobile, which is said to be the first introduced into Ireland. It is driven by a Serpollet steam motor and was on exhibition in the hall in which the lecture was given. In addition to the carriage itself, Mr. Brown employed to illustrate his lecture a numerous collection of lantern slides showing the history and development of this recent application of mechanical ingenuity. At the end of the lecture, which was received with great enthusiasm, the following resolution was passed: "That this meeting approves of the proposed modification of the Locomotive Acts so as to promote the use of mechanically propelled carriages on public roads, subject to suitable provisions for the safety and convenience of the public." The Lord Mayor, who is one of the partners in the great shipbuilding firm of Harland and Wolff, said it was a matter of extreme regret that while great developments had taken place during recent years in mechanical contrivances for a variety of purposes, in one particular—that of horseless carriages—British skill and enterprise had not only been discouraged, but positively checked and thwarted by an antiquated Act of Parliament that should have been repealed long ago. It is hoped that at the next agricultural show in Belfast, at the end of June, we may have an exhibition of these horseless carriages.

The Abuse of Hospitals.

I understand that the secretary of the Belfast Hospital for Sick Children has sent a letter to the members of the medical profession in Belfast stating that as it has been reported that cases unsuitable for treatment at that hospital from time to time present themselves the medical staff will feel obliged if the name and address of any such cases will be reported to him so as to assist the medical officers in preventing abuse of the charity. The extern department of this hospital has of late increased to a very great extent and there can be no doubt that numbers of patients receive advice and medicine who could quite well pay a small fee to the hardworking medical men of whom there is such a large number in Belfast.

The Proposed New Derry Asylum.

With reference to the proposed erection of a new asylum at Londonderry at a cost of about £20,000, one of the Limavady guardians, at the last meeting of that board, held on April 20th, introduced the subject by stating that if this new building were erected the cost would fall entirely on the agricultural community of the county Derry and would mean an increase in the rates of from 4*d.* to 5*d.* in the pound, which was a very serious matter and of great importance to them all. He said the present Derry Asylum had cost a great deal, and during the last eleven years there had been in all £29,066 expended on it, which amount, repayable in fourteen years,

Digitized by Google

meant £2652 annually. He suggested that arrangements should be made to reduce pressure on the present asylum by distributing all the harmless lunatics over the different workhouses in the county, and so to obviate the necessity for incurring the enormous expense of building a new asylum. They might easily find room in the Limavady Workhouse for 100 or 150 of the harmless lunatics at present in the Derry Asylum. After some discussion a resolution was passed to the effect that, owing to the existing agricultural distress and the additional expenditure that it would entail in erecting a new asylum, all action in that direction for the present be suspended, and that the Limavady board of guardians offer to give accommodation for 100 to 150 harmless lunatics in their workhouse. It was suggested that other unions in county Derry might join with the Limavady guardians with a view to reduce the present pressure on the Derry Asylum.

Belfast District Lunatic Asylum.

From the sixty-sixth annual report of the resident medical superintendent (Dr. Merrick) of the Belfast Asylum I find that during the year the daily average number resident has been 782, an increase of 59 over that of the preceding year. During the year 240 patients were admitted, the highest number of annual admissions recorded in connexion with the asylum. On Dec. 31st, 1895, there were 698 cases in the asylum, while the normal accommodation is 400; hence the difficulty of proper treatment and classification is apparent. It is curious that melancholia figures largely in the admissions, there being 78 cases suffering from this condition. Of these, 11 had made suicidal attempts and 53 were noted in their admission forms as having suicidal tendencies, thus needing special supervision. Eight cases required forced alimentation due to voluntary abstinence. There has been a larger proportion on the sick list than in previous years. Forty males and fifty females were discharged recovered, and forty cases were sent out improved during the year. There were 44 deaths. The general health of the patients, excepting delicate cases, was most satisfactory, and no case of contagious or infectious disease occurred. Regarding the great overcrowding of the asylum Dr. Merrick urges the completion of even two blocks in the County Antrim Asylum, which would provide accommodation for 200 county patients, and if this were supplemented by the erection of the proposed buildings at Purdysburn to accommodate 300 chronic patients the present overcrowding would not only be relieved, but improved classification of the patients could be adopted, their condition made more comfortable, and better opportunity afforded for improved treatment. The gross expenditure of the asylum for the past year was £18,307 10*s.* 10*d.*, and if £7236 1*s.* 4*d.*, the amount of the Government grant received, and £1043 18*s.* 2*d.*, the amount received from miscellaneous sources, paying patients, farm and garden, &c., be deducted, it will give £10.027 11*s.* 4*d.* as the net amount chargeable to the rates of the district, or £12 16*s.* 5*d.* per head. The net yearly cost per head (including every charge of management) was for the past year £22 1*s.* 6*d.* The inspector of lunatics and commissioner of control (Mr. G. R. O'Farrell), in his memorandum of inspection on Nov. 1st, 1895, says he believes that no public institution in the United Kingdom is at the present time more overcrowded than this asylum; yet he found every department orderly and clean, while its bill of health was favourable and its mortality-rate very low. Certainly, as the inspector says, "With such perilous surroundings, with dormitories so full that there is scarcely space for beds, the resident medical superintendent deserves the greatest credit for his good and careful management of the institution. Dr. Merrick is ably assisted by the assistant medical officer, who shows much energy and practical zeal in the discharge of his duties."

The Mitchelstown Union Hospital: Alleged Ill-treatment of Patients.

About two months ago a trained nurse was appointed to take charge of the Mitchelstown Union Hospital. She had been there only a few weeks when she sent in her resignation and alleged that some of the patients had been beaten by one of the nurses. The guardians held an investigation, and if the statements made by some of the inmates be true a very serious state of affairs must have existed for some time. An old man eighty years of age told the chairman that he had been struck, and that on asking the nurse to allow him to remain in bed she dragged the clothes off him and left him naked. It was also stated that the same nurse had struck another old man when in bed with a poker on the knees and afterwards thrown him down stairs. It was also alleged that she had knocked down a patient and kicked him. The resigning nurse stated she had endeavoured to put an end to such conduct, and as she had found things so generally unpleasant she had finally decided on leaving. Many of the guardians considered they owed a debt of gratitude to the nurse, and a resolution was passed calling on the Local Government Board to hold a sworn investigation with a view to thoroughly sifting the matter.

Triennial Visitation at the Queen's College, Cork.

A triennial visitation will be held at the Queen's College, Cork, to-morrow. It is expected that the Presidents of the Royal Colleges of Physicians and Surgeons will be present and that Mr. Justice O'Brien will preside. A Medical Students' Association has been recently formed at the College, and the association has requested the College council to make certain alterations in connexion with the medical school. It is stated that some of the requests have been granted and others are still under consideration, but with the impetuosity characteristic of youth the students think that their views should have been adopted by the council at once, and accordingly they intend applying to the visitors, who form a court of appeal, to issue a direction to the council with regard to any of the requests which have not been acceded to. The students have engaged the services of a solicitor, and in medical circles the proceedings are looked forward to with interest.

April 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Castration in Egypt.

M. LORTET recently exhibited before the Société de Médecine of Lyons the skeleton of a eunuch of Cairo, which skeleton measured 1 metre 96 centimetres. The thorax appears very short as compared with the exceptional length of the legs. This phenomenon is quite in accordance with what is met with in the lower animals. Thus, while the wings of a capon are no more highly developed than those of a cock, the long legs impart to the emasculated fowl a peculiar appearance. This same lengthening of the hind limbs in the ox corrects the sloping of the back-line which is so characteristic of the bull. M. Lortet furnished some interesting if not very savoury details concerning the operation of castration as currently practised on Egyptian boys from seven to ten years old. One method consists of the amputation of the penis and scrotum close to the pubis by one sweep of a razor. The poor child is then plunged up to the neck in fine dry sand, the compression thus brought to bear on the wound contributing to arrest the hæmorrhage. At the end of four or five days the patient is removed from his sand-bed and the wound is dressed with rags soaked in oil. Another method employed is the application around the spermatic cord and the penis of a very fine, strong ligature tightly tied. The sufferings of the unfortunate victim can easily be imagined, but hæmorrhage is less to be feared than by the cutting method. The subsequent burying in sand is in this case dispensed with, the only dressing applied being the bark of acacia rich in tannin. But whichever of the two barbarous proceedings be adopted it is said that two-thirds of the children succumb. The suppression of such a cruel practice will in time constitute one of the numerous blessings accruing to this ancient race from the British occupation of the country.

The Sero-therapic Treatment of Puerperal Fever.

Readers of THE LANCET will probably remember that on Feb. 23rd, 1895, M. Marmorek communicated to the Société de Biologie his discovery of an antistreptococcic serum, and that on the same occasion M. Roger and M. Charrin made a similar communication, besides reporting a case of puerperal fever said to have been cured by their serum. M. Roger afterwards reported a second successful case, and later still the cure of a case of erysipelas of the new-born and of a case of streptococcic tonsillitis by injection of his serum. Then M. Marmorek announced the successful treatment by his serum of 45 adult cases of erysipelas. M. Charpentier[1] has collected 40 cases

[1] Société Obstétricale de France, April 10th.

Digitized by Google

of puerperal septicæmia treated by serum in the different maternity departments of Paris hospitals and in private practice. The results were 22 recoveries and 17 deaths, or a mortality of 42·5 per cent. Deducting 5 cases treated *in extremis* and 1 where the result was vitiated there still remains a death-rate of 35·29 per cent. Bacteriological examination was conducted in 25 instances, the streptococcus being discovered in 16 cases (9 recoveries and 7 deaths), and the streptococcus associated with the staphylococcus or the bacterium coli in the remaining 9 cases (4 deaths and 5 recoveries). The dose of serum injected varied within wide limits. In no instance was the serum treatment trusted to exclusively, intra-uterine medication being also employed. Urticaria, erythema, pruritus, and divers symptoms of a nervous order were frequently noted as the result of the injections. M. Gaulard of Lille attributes one death in his practice to the serum. M. Budin is inclined to deny the utility of the method, and M. Charpentier states that the high hopes inspired by the discovery have not been fulfilled. M. Bar and M. Tissier have treated 19 cases with Marmorek's serum with 10 deaths and 9 recoveries. Eliminating 3 cases where the treatment was instituted *in extremis* and 3 in which no bacteriological examination was made, there remain 13 well-studied cases with 6 deaths. In 6 cases treated by serum prepared by M. Roger and M. Charrin, and eliminating 1 case not examined bacteriologically, 4 out of 5 died. Four cases of erysipelas in the new-born died in spite of the employment of the serum. The serum appears to be too weak to neutralise the toxines in cases of general infection, although in ordinary cases of adult erysipelas it is efficacious. M. Bar thinks that the injections are commenced too late in puerperal cases. The strange recommendation of M. Marmorek to refrain from all intra-uterine medication has been discarded by all practical gynæcologists. M. Bar has never seen albuminuria occasioned by the serum, but other symptoms more or less grave have been noticed. Once an abscess formed and, strange to say, large numbers of streptococci were discovered in the pus. A woman treated at St. Louis Hospital received about 100 c.c. of serum in twenty days. Four days after the last injection the temperature diminished gradually, and debility finally induced a fatal result. It is evident that once puerperal fever has made any progress we cannot count upon the serum any more than we can upon other better-known methods of treatment. M. Charpentier wound up the discussion by remarking that when intra-uterine treatment was applied at the very commencement a good result invariably followed. All this is disappointing, but it only means that the serum, if it is to justify the expectations promised by its discoverers, must be made more active and safer to manage. It may, after all, be *the* remedy of the future.

April 21st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Alleged Fatal Injection of Diphtheria Antitoxin.

A GREAT sensation has been caused by the recent announcement in the births, marriages, and deaths columns of the principal Berlin newspapers that a child, one and a half years of age, had died "from inoculation of diphtheria antitoxin"; the same subject was moreover continued on the following day by an intimation of the burial of the "poisoned" child. As the father, who had inserted these paragraphs, was a very well known medical man, Professor Langerhans, prosector to the Moabit Hospital and a former assistant to Professor Virchow, the public naturally became alarmed, and the lay press discussed the matter in detailed articles, of course before any particulars were known. By order of the legal authorities a post-mortem examination of the body was made by two medical officers attached to the law courts, but the cause of the death could not be clearly defined. As already mentioned in your columns,[1] the serum was seized by the authorities, but I learn that it was ascertained to be of normal quality and that it had been already used for other patients without any accident. It is now stated that the injection was made for prophylactic reasons because a servant of Professor Langerhans had been attacked with alleged diphtheria and admitted to the Moabit Hospital. The injection was performed by the father himself, and the child died from asphyxia three minutes afterwards. It is, of course, quite impossible to attribute this sudden death to the serum, as hardly any poison except hydrocyanic acid can destroy life so promptly. The complications hitherto described as resulting from antitoxin have always happened long after the injection, and no permanent ill-effect from it has hitherto been recorded. The abdomen is stated to have been the site of the injection, and very probably death was due either to entry of air into a vein or to thrombosis. The whole proceeding was subsequently proved to have been quite unnecessary as the servant's illness was found at the hospital to be simple tonsillitis and not diphtheria. Professor Eulenburg, the editor of the *Deutsche Medicinische Wochenschrift*, has given his opinion in most energetic terms both in his own journal and in a widely read non-medical weekly paper. The medical profession is unanimous in blaming Professor Langenhans's course of action, which can only be explained on the ground of his mental anguish.

[1] THE LANCET, April 18th, p. 1081.

Medical Courts of Honour in Prussia.

In THE LANCET of June 1st, 1895 (p. 1404), an account was given of a Bill brought before the Saxon Parliament relating to ethical misdemeanours committed by medical men. Prussia, the greatest of the German States, now has a Bill very like that of Saxony, but much more stringent. Its principal feature is that every provincial medical board shall elect four of its members who, together with a learned judge, will form the "court of honour." They will inquire into alleged contraventions of medical ethics and will also act as mediators in disputes between medical men. A Government lawyer will act as public prosecutor, whilst the defendant is entitled to be legally represented. The court of honour is invested with the same privileges as an ordinary law court; it may, for instance, compel the attendance of witnesses, but the proceedings are not public, only the members of the medical board being entitled to be present. The penalties are either simple warning, reprimand, or a fine not exceeding 3000 marks (£150). A court of appeal is, moreover, to be instituted in Berlin, consisting of the director of the medical department of the Home Office as president, three other members of this department appointed by the Crown, and three representatives of the medical boards elected by its members. The subject of ethical misdemeanours has for long been an anxiously discussed question at medical gatherings, but nothing was done, as the Government refused to allow the courts to have jurisdiction over the medical officers of the army and civil service. The invidious exemption of these medical officers, which is maintained in the new Bill, together with the introduction of the official element in the shape of the public prosecutor and the court of appeal, is looked upon with distrust, and it is the opinion here that medical men should be entitled to settle questions of etiquette and ethical misdemeanours among themselves without the intervention of Government officials. Some of the sections of the Bill will possibly be altered by Parliament, but the principal points, especially the exemption of the medical officers of the services, will certainly become law.

The late Dr. Baum.

Dr. William Baum, chief surgeon to the General Hospital in Dantzic, Western Prussia, died in that town on April 13th. As a military surgeon he took part in the wars of 1864, 1866, and 1870–71, and on the conclusion of his military service, in which he distinguished himself by his great ability, he was elected surgeon to the Dantzic Hospital. He not only conducted a very extensive practice, but wrote on many subjects, including ovariotomy, cancer of the uterus, resection of the nerves, emphysema, &c. He was universally esteemed by his fellow-citizens and the profession.

April 21st.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Kassala and the Rumoured Prevalence of Malaria.

ONE must take with a good many grains of salt the "intelligence" that appears from French sources as to the Anglo-Egyptian, and more especially the Italian, movements in the Soudan or in Abyssinia. According to the *Italie*—French in language and aspiration though published here—

Digitized by Google

Kassala is a centre of malarial infection and the Italian soldiers which garrison it are attacked with the fever at the rate of 500 a week. In these circumstances the Dervishes have only to wait a little and their malarial auxiliary will do for them what their siege operations have hitherto failed to accomplish—effect an evacuation of the stronghold. Information, however, from the commandant of the Italian force quartered at Kassala, communicated on the eve of the battle of Abba Carima and since then confirmed, gives a totally different account. The hygienic conditions of the garrison differ in no respect—certainly not for the worse—from those prevailing at other centres of the Colonia Eritrea. I may add that its defensive resources are still unimpaired, which cannot be said of the offensive power of the enemy.

Dr. Baccelli's Return to the Chair of Clinical Medicine.

The ex-Minister of Public Instruction resumed his professional duties on the 13th inst. in the clinical amphitheatre of the Santo Spirito Hospital before a brilliant audience. Besides the 500 students for whom it is seated the amphitheatre contained many physicians and consultants of the city and province, to say nothing of distinguished medical visitors, mostly German, on their way through Rome. Dr. Baccelli always shines on these occasions, and his ἔπεα πτερόεντα (winged words) found their way to every heart as he described his two years' Odyssey on the troubled waters of political life and his finding himself once more in the academic Ithaca of former and better days. Passing in review the advances made by medicine since their last meeting, he once more warned his young hearers not to be seduced by scientific research, however fascinating, from their proper place at the bedside, where alone the "diagnostic eye" and the "tactus eruditus" can be trained, till disease surrenders itself unconditionally to the physician who can read its "expression," run it down through all its protean shapes and compel it almost to suggest its proper treatment and cure. Not that he depreciated the knowledge and the mental discipline gained in the *palæstra* of the laboratory. Far from it. "La medicina è un' arte che deve essere illuminata dalla scienza" (medicine is an art which ought to be lighted up by science), but an art it will always remain, and its most successful practitioner an "artist" in the highest and most ideal sense of the word. From this he passed to the evil which seems to beset practice at the present moment—the "polifarmacia" (the excess of reliance on "remedies"), which has usurped the place of the equally objectionable "nihilismo" ("do nothing" system). Having illustrated the evils of both and vindicated the *via media* of an enlightened caution, he proceeded to the clinical business of the day—the diagnosis and treatment of abdominal abscess, particularly when affecting the parietes. At the close the repeated rounds of applause evoked from him a few supplementary words, not less felicitous than those of the preamble, on the conduct of pupils of the Roman school in recent hours of danger and death on the stricken field, conduct worthy of the best days of the Mistress of the World.

April 18th.

Obituary.

MARIANO SEMMOLA.

THE profession in Italy, and, indeed, throughout the world, has lost an able and exemplary investigator, teacher, and consultant in the Professor of Clinical Medicine in the Neapolitan School. Mariano Semmola is no more. He died in Naples on the 5th inst. of a second apoplectic seizure, the first having overtaken him on March 8th. From this he had made a partial recovery. The intellect continued intact, the hemiparesis confined to the right arm had disappeared, but the aphasia was persistent. On the 29th ult. the hemiparesis recurred, involving half the right side and the bladder; but all the skill of his colleagues failed to alleviate the symptoms. He steadily grew worse, though the mental faculties remained clear and the spirits serene to the end, which supervened, as stated, on the early morning of the 5th. He came of a medical family, and particularly in his illustrious father, Giovanni Semmola, he had an ideal of what the hard-working, sagacious physician can do. There was no branch of the healing art in which the elder Semmola did not leave a memorable impress, and his son proved what he aspired to be, a worthy professional heir. Born at Naples on Jan. 31st, 1831, he passed through a brilliant curriculum, literary, philosophic, and medical, under teachers like Guarini, Gasparrini, Tenore, and Palmieri, distinguishing himself in the weekly *résumés* of work when student was pitted against student in competitive exposition, and impressing his clinical chiefs with his powers of getting at "the root of the matter." When twenty years old he presented to the Accademia di Medicina di Napoli three papers on Bright's Disease and Albuminuria, and brought out in a striking manner the great influence of the azotized and non-azotized regimen on the quantity of albumin eliminated by the kidney in the twenty-four hours by sufferers from morbus Brightii. Proceeding to Paris he plunged into steady work, experimental and clinical, under Rager, Trousseau, and Bernard, and earned the plaudits of a distinguished auditory at the Institut for a monograph on Pathological Glycogenesis. On his return to Italy he resumed, with increased knowledge and unabated ardour, his studies in albuminuria, a subject with which, from 1861 to 1893, his name has been identified by numerous papers read before scientific bodies and medical congresses, national and international. In 1883 he had so favourably impressed the Paris school by what he had contributed to the pathology and therapeutics of the subject that at its instance the French Government decorated him with the "Legion of Honour" and the Académie de Médecine elected him corresponding member. Controversy was not spared him in this arduous field of research, and his findings were contested by Senator of Berlin and Labadie-Lagrave of Paris, but not without ample recognition on their part of the independence and sagacity of his work. His ambition was to revive the mediæval pre-eminence of Italian medicine, and with that view he founded the Archivio Medico Italiano, in which all research and observation, clinical and therapeutic, was welcome on the one condition that it was national in its authorship and independent in its tenour. In 1869 he gave to the world his "Terapia Empirica e Terapia Scientifica," and in 1877 his "Medicina Vecchia e Medicina Nuova," the latter so bright and attractive a piece of exposition that it was speedily translated into most European languages, including English, German, French, Portuguese, and Greek, while as late as 1891 his permission was asked and given for his coöperation in rendering it into Russian. In 1890 appeared at Berlin the German translation of his "Prolegomeni di Farmacologia e di Terapia Clinica," preceded by a brilliant preface from the pen of Professor Nothnagel of Vienna. His was one of the few sceptical voices that broke the outburst of enthusiasm with which Koch's experiments on the bacillus of tubercle and its counteracting lymph were hailed, his attitude towards sero-therapy as a whole being one of approval, vigilant indeed and cautious.

Academic employment came to him early and in abundance. In 1865 we find him in the chair of Pharmacology and Therapeutics in the University of Naples, to which he attracted crowds of students; and in 1866, at the instance of Baron Ricasoli, then Minister of the Interior, he took part in the Royal Commission charged with the new Codice Sanitario Italiano, in which his coadjutors were Cannizzaro, Bô, and Burci. In 1874, on the invitation of the Italian Government, he represented Italy at Vienna in the International Sanitary Conference convened to revise the recommendations of the previous conference held at Constantinople, and to formulate measures of international application for the averting of cholera and other Eastern epidemics. His participation in the discussions was marked by such knowledge, discrimination, and expository power that his speeches were reproduced *in extenso* by the leading scientific journals, and the further honour was conferred on him of knightly decorations at the hands of foreign Powers, including Russia, the Czar *proprio motu* and with an autograph letter bestowing on him the badge of Grand Officer of S. Stanislaus. On his return from Vienna he was nominated Member of the Consiglio Superiore di Sanità of the Italian kingdom and afterwards be became President of the Croce Bianca, in which capacity his exertions during the great cholera epidemic in Naples were second only to those of the King, by whose side he worked night and day. For this service he received the gold medal of Valore Civile. He represented Italy at the International Medical Congress held at Brussels (1875), Amsterdam (1879), London (1881), Copenhagen (1884), Rome (1885), Washington (1887),

Digitized by Google

and Berlin (1890). In 1883 the then Minister of Public Instruction, Signor Coppino, founded the chair of Clinical Therapeutics, of which he became Professor, and in 1888 his lectures so impressed Don Pedro, the Emperor of Brazil, then a casual auditor, that when his Imperial Majesty fell ill the same year at Milan he would have no other consultant than Dr. Semmola, who remained in attendance for two months. In one of the graver crises of that memorable illness Dr. Charcot was summoned by telegraph from Paris, but on examining the illustrious patient and finding what had been done he declared that his presence was not required, every available means having been adopted by Semmola, whom he congratulated on the skill and success of his treatment. The Emperor, re-established in health, showed his gratitude not only by one of the handsomest *honoraria* on record, but by conferring on the Neapolitan physician the Grand Cordon of the Imperial Order of the Rose, while the municipality of Rio de Janeiro presented him with a gold medal specially struck for the occasion and also with an address of congratulation. In 1890 he was called in consultation at Constantinople by the ex-Khedive of Egypt, his Imperial Highness Ismail, remaining in attendance three weeks, during which he availed himself of his presence in the Turkish capital to deliver before its Academy of Medicine a memorable discourse on Albuminuria and Nephritis. This he followed up at the "Syllogos Litterarius" of Constantinople by a lecture on the Physiological Cure of Diseases, in consideration of which the Sultan decorated him with the Grand Cordon of the Osmanlie.

In Parliament he represented Caserta in the Liberal interest, and was always heard with equal interest and profit on questions of public health and public instruction. In 1886 he was nominated Senator of the kingdom. With all this professional and public activity he was a prolific writer, his publications (to say nothing of contributions to medical periodicals) including treatises on Diabetes Mellitus, on the Calabar Bean, on Addison's Disease, on Gastropathia Nervosa, on Cardiac Neuropathy, on Iodoform and its Uses, on "Saturnismo Cronico," and on Hydatid Cysts of the Liver. In THE LANCET of Sept. 14th 1895, appeared his paper on "The Antisudorific Properties of Picrotoxine." His funeral, on the 6th, was a public one, the chief commercial houses in Naples suspending business for the occasion, and a vast multitude of mourners, including every class of society, accompanying him to the grave. *Oraisons funèbres*, eloquent and touching in their tenour, were delivered by his surviving colleagues, among whom may be mentioned Professor Armanni, Professor Vizioli, and Dr. Renzi, while Dr. Ferrara, Dr. Matoni, and the Senator Dr. Martini spoke for the profession and the Legislature with equal power and effect. Telegrams of condolence with his family continued to arrive from all parts of Italy and from most of the European capitals, unanimous in deploring the loss of one of the greatest of Italian physicians and teachers, whose professional enthusiasm was hardly more conspicuous than his sense of public duty and his exemplary virtues as a citizen.

JOHN GASON, B.A. DUB., F.R.C.P., L.R.C.S. & L.M. IREL.

FOR more than fifty years this active and philanthropic practitioner divided his professional year between Rome and the Baqui di Lucca, practising in the Italian capital during the winter and spring and in the Tuscan health resort during the summer and autumn. Born in the county Wicklow he proceeded, at the early age usual in Ireland, to Trinity College, Dublin, where he completed his education in arts by graduating B.A. in 1836. He thereafter enrolled as a student of medicine in the Dublin school, took the Licentiateship in surgery and midwifery at the Royal College in 1839, and five years later the analogous qualification at the Royal College of Physicians, of which in 1863 he became Fellow. In 1845 he repaired to Rome and in the Anglo-American colony there continued to practise till well past his eightieth year, not only attending to his private *clientèle*, but interesting himself in the medical charities under British support. Among these he was consulting physician to the Anglo-Italian Protestant Dispensary and medical director of the Protestant Hospital, both of which institutions owed much to him, not merely for professional attendance unremittingly bestowed, but also for effective support, pecuniary and other. The British Relief Fund also could invariably count on his coöperation, medical and philanthropic; while among other services to the English-speaking colony he was mainly instrumental in erecting Trinity Church in the Piazza di San Silvestro—the first place of worship for members of the Church of England opened within the city walls. As the dean of the English-speaking practitioners and consultants in Rome he had many opportunities of showing kindness and hospitality to professional brethren from Great Britain, America, and the colonies—opportunities by which many profited, particularly during the Cholera Conference of 1885 and the Eleventh International Congress of Medicine and Surgery in 1894. Up to within the present year he continued in his customary vigorous health, till within the last few days he succumbed to an apoplectic seizure. He was interred on the 17th inst., by his special desire, at the Baqui di Lucca, where, no less than in Rome, he has left the English-speaking public indebted to him for kindly and valuable services extending over half a century.

WILLIAM SQUARE, F.R.C.S. ENG., L.R.C.P. LOND., L.S.A.

THE death is announced of Mr. William Square, whose name for many years has been prominently identified with the medical profession at Plymouth, Devon. He died on Saturday, April 18th, after an extremely short illness. He was educated at Rugby and the Baptist College, Regent's-park, London, and matriculated when he was sixteen years of age at the University of London. He commenced his medical studies at the South Devon and East Cornwall Hospital and continued them at St. Bartholomew's Hospital, where he took several prizes and was senior scholar for the year 1866. He became M.R.C.S., L.S.A. in the same year, L.R.C.P. in the following year, and F.R.C.S. in 1871. He was elected a Fellow of the Royal Geographical Society on the nomination of Sir Leopold McClintock and General O'Connor. For a number of years, and up to the time of his death, he held the position of surgeon to the South Devon and East Cornwall Hospital, having been appointed to that position on the retirement of his father. He was also senior surgeon to the Plymouth Royal Eye Infirmary. Last year he filled the presidential chair of the Plymouth Medical Society, one of the oldest societies of its kind in the kingdom, it having been established in 1794. For twenty-five years he was honorary surgeon to the Plymouth Fire Brigade. The deceased gentleman was a great traveller, one of his latest expeditions being to the Pyramids of Egypt. He was gifted with an extraordinary memory and was a genial companion and a versatile conversationalist. Although a very good *raconteur* he never told a story against anyone or uttered an ill-natured expression. He was an ardent sportsman, and claimed to have taken part in the first swimming match in Plymouth, whilst as a fisherman, and more recently as a cyclist, his imprudent disregard for the safety of his own health proved a constant source of anxiety to his friends. To give pleasure to others was his greatest delight, and for this he would sing a song, tell a tale, work up a lecture and spare neither time nor money in arranging some theatrical performance or in arousing interest in some philanthropic movement. He was an enthusiastic horticulturist. Mr. Square, who was for a short time a Plymouth town councillor, was only fifty-two years of age, and his untimely death will be greatly mourned.

EDWARD DAY MCNICOLL, F.R.C.S. EDIN., L.R.C.P. EDIN.

A FEW months ago Mr. McNicoll was apparently in perfect health. He was then attacked by pain, at first put down to sciatica, which kept him to bed for a short time; but he was soon again visiting his patients. Before long, however, it was evident that something more serious existed and he was found to be suffering from sarcoma. His painful and hopeless illness was borne with cheerful fortitude and a marvellous patience, and all that skill and kindness could suggest was done by medical friends to relieve his sufferings until his death, on the 14th inst., at the age of fifty-one. He was born in 1844, and was the second son of the late D. H. McNicoll, M.D., of Southport, who was a man of considerable and varied attainments. It was at first intended that Edward McNicoll should be an engineer, but towards the close of his apprenticeship to a firm at St. Helens he decided to follow his father's profession. In

Digitized by Google

1873 he became L.R.C.P. Edin., and some years later the Fellowship of the College of Surgeons, Edinburgh, was conferred upon him. He practised for twenty-three years in Southport and for some years was in partnership with Sir George Pilkington, now retired from practice. He had a large general practice, was an honorary medical officer of the Southport Infirmary, which benefited much from his untiring exertions on its behalf, and at one time was resident medical officer to the Southport Convalescent Hospital. He was always a kind friend to the poor, and the extent of his benefactions will never be known. His busy life allowed little time for literary work, but he was an occasional contributor to the medical journals, and some years ago edited a new edition of his father's "Handbook to Southport," which contained valuable information as to the fauna and flora of the districts. Mr. McNicoll never married, but leaves an aged mother and two unmarried sisters in the home of which he was the brightness and the stay. His death is much mourned in Southport, where he was universally esteemed, and indeed beloved, for his was a singularly winning nature, and no one could see his open ruddy face, with its genial expression, without feeling that he was in the presence of a kindly, unselfish, and honest man. His medical brethren in large numbers and a great concourse assembled round his grave. Mr. Wm. Heath, Dr. Baines, and Dr. Baildon were unwearied in their attention to their friend, and he was seen also by Mr. Banks and Mr. Paul of Liverpool and Dr. Bill of Edinburgh, who could only endorse the unfavourable prognosis already given.

ALFRED GEORGE ROPER, F.R.C.S. ENG.

ALFRED GEORGE ROPER of Croydon passed away at Croydon at the age of seventy-seven years, on April 13th. He was educated at Guy's Hospital and obtained his M.R.C.S. and L.S.A. in 1840, and became a F.R.C.S. in 1875. For forty years he was in practice in Croydon, and was held in high esteem by all his fellow practitioners. For thirty-one years he was surgeon to the Croydon Infirmary and did much towards the arrangement of the present infirmary, receiving a suitable acknowledgment from the guardians for his valuable services. In 1867 he promoted the Croydon General Hospital, and acted as its senior surgeon and honorary secretary for some years, and in 1875 received a handsome public testimonial in appreciation of his honorary services to this institution which through his energies has become what it is. He leaves a daughter and three sons, one of whom is in the medical profession.

CHARLES HIGHETT, M.R.C.P. EDIN., L.S.A.

MR. CHARLES HIGHETT, M.R.C.P. Edin., L S.A., died at his residence, Field House, Montpelier, Bristol, on April 20th, aged eighty-four years, having been for some time in a delicate state of health. Mr. Highett was educated at the Bristol and Middlesex Hospital Medical Schools, and took the L.S.A. in 1840, the L.R.C.P. Edin. in 1860, and the M.R.C.P. Edin. in 1865. He was descended from an old Huguenot family, and married the eldest daughter of the late Dr. Spencer, ex-Mayor of Wells, who died many years ago. Mr. Highett settled as a medical practitioner in Bristol fifty-four years ago, but did not remain long in active practice. It was not until comparatively late in life that he took a prominent part in municipal matters. In 1881 he obtained a seat for the district ward, and attended regularly to Council work, being an active member of the Sanitary Committee and also of the Finance and Library Committees. He was elected Mayor in 1891 and most efficiently discharged the duties of this office. During his mayoralty Mr. Highett was elected to a vacancy on the aldermanic bench. He was an earnest Churchman, of a kindly and courteous disposition, and a good friend to the poor. His fellow citizens held him in the highest esteem and much regret his death.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Constantin Paul, *Professeur Agrégé* of Therapeutics and Member of the Paris Academy of Medicine. He was President of the Therapeutical Society and an accomplished clinical physician. His works, which are numerous, are largely devoted to the subject of the effect of treatment on cardiac disease. — Dr. Pietro Gamberini, Emeritus Professor of Dermatology and Syphilis in the University of Bologna.—Dr. Ramakers, Assistant Professor of Anatomy and Physiology in the Algiers Medical School.—Dr. Luton, Professor of Clinical Medicine in the Rheims Medical School.

THE

INTERCOLONIAL MEDICAL CONGRESS OF AUSTRALASIA, 1896.

FOURTH SESSION.

(FROM OUR SPECIAL CORRESPONDENT.)

(*Continued from page 1107.*)

THE SECTIONS.

PUBLIC HEALTH.

PRESIDENT'S ADDRESS.

THE presidential address in this section was delivered by Mr. SPRINGTHORPE, and he took for his subject a Physician's View of the Battle of Life. The battle itself, he said, has to be waged man against man, man against other forms of life, and man against himself. The domain of the strife of man with man was well recognised and there was no escape from the law of the struggle for existence. Spinoza reminds us, he continued, that the big fish were created to swallow the little fish, and the incessant border warfare of savage tribes shows how well man fulfils his destiny. The civilised man follows the same law, though in different manner. Society, to quote again from Spinoza, is simply an organisation of the little fishes to protect themselves, and the strife continues between individuals, classes, and races. Against such natural law the decrees of statecraft and the educated selfishness of coöperation are but partial and temporary expedients, and, fortunately perhaps, the physician is called in simply to help the fighter to fight better; whilst in the "battle of the clubs"—the struggle for practice—he himself experiences its keenness. Will competition, then, never be restrained except by self-interest? Not, perhaps, from the material and vital sides, but surely by the development and spread of those higher considerations which some think are foreign to those lower relationships and depend entirely upon man's peculiar moral endowment. Man's conflict with other forms of life, however, is a subject more pertinent to the physician. As we have seen, the great law of the struggle for existence rules not only individuals but species, genera, classes, and kingdoms. For his sport, use, or food man preys upon the lower animals, and wherever practicable the latter returns the compliment. In parasiticism we find an even closer interdependence and strife, each harbouring at its own risk certain organisms which may affect the other; they may be air, food, or drink. It would surprise many who have not carefully studied the question to find how numerous and important are the diseases thus produced and how large the number of human beings thus affected. For the present, putting on one side the question of germ diseases, man acts as the host of eight protozoa, fifty-one helminths, and twenty-one arthropods. There are reasons, more or less strong, for associating cancer with protozoic invasion. The common round worm, the guinea worm, the ankylostoma, and the megastoma are all found in the intestines of other animals as well as man and are undoubtedly interchanged from one to the other. In the different tapeworms—the beef tapeworm, the pork tapeworm, and the hydatid—we have alterations of form and effect with the difference of habitat, the mature forms inhabiting the intestine and the larval condition being assumed in the internal organs. The trichina again, which is the real cause of many epidemics variously described as poisoning, rheumatics, typhoid fever, typhus fever, and formerly as black death and English sweat, exists in man in both developed and undeveloped states, whilst the hog is its peculiar and original host. The disease thus produced is both extensive in amount and varied in manifestation, and though some of the forms at least are well recognised there is often need of special inquiry as to their possible presence in all obscure cases of nervous or intestinal disorder attended with anæmia and emaciation.

Digitized by Google

Not unnaturally, perhaps, it has become too much the custom to regard all microbes as injurious, forgetful of the fact that there is another side to these activities, as is exemplified in their being Nature's scavengers and earth's fertilisers, bakers of man's bread, brewers of his beer, makers of his vinegar, and flavourers of his wine, butter, and cheese; indeed, without the presence of friendly germs in his intestinal flora his food would not be peptonised and in the midst of plenty he would starve. Another common error is the supposition that the invasion of the germ necessitates the production of the disease. This is no doubt true in certain cases, such as anthrax and certain pyococci, but it is generally the constitutional state rather than the presence of the germ which determines the extent of infection, the issue of the fight; hence, while doing all that is possible to prevent invasion, and even attempting to kill the germ so far as is possible without injuring the combatant tissues, it is still more important to fortify the outposts by promoting the healthy condition of the mucous membranes and bathing them in healthy secretions, and to build up the natural resisting power of the organism as a whole. And as the resisting power varies so also does the virulence of the germ, both towards aggravation and towards attenuation. Nor is the struggle simply between man and germ; it rages equally between germ and germ, and mixed infection is by no means uncommon. As Dr. Lauder Brunton graphically reminds us: "Even amongst these minute organisms the struggle for existence and the survival of the fittest exists. When two microbes are growing together one may choke or destroy the other, just as weeds in a garden may choke the flowers. On the other hand, successive generations of the microbe may render the soil unsuitable for another, just as decaying algæ and mosses may furnish mould in which higher plants can grow. The struggle takes place also between the disease germs and the cells of the organism which they have invaded. This has been beautifully shown by Metchnikoff in the Daphne, where the process of the cells eating up the microbes or the microbes destroying the cells can be actually observed under the microscope. It is impossible to see one part of a microbe half digested whilst the part outside remains unaltered without believing that the process of phagocytosis is one of great importance. At the same time it bears about the same relationship to the total struggle that a bayonet charge bears to a modern battle. The main part of the fight is really carried on at some distance by deadly weapons, by bullets in the case of the soldier and by ferments, poisonous albumoses, and alkaloids on the part of cells and microbes." Even this description by a master hand is not altogether complete. It says nothing of the immunity that may be artificially built up for a limited period by various manipulations of the germs themselves and of the antitoxins which the system throws out in its hour of peril, which, strength for strength, are the exact chemical antidotes to the toxines, and the recent application of which in various disorders has been the crowning therapeutic triumph of the century. We are thus prepared for the perhaps surprising fact that it takes two factors—germ and susceptible organism—to produce the disease, and that the germ alone may be present in mucous membranes, tissues, air, food, or drink without any necessary appearance of the disease. On the contrary, there cannot be the disease in the absence of the germ. The list of diseases thus produced is a long and weighty one. The bacteriologist is thus an essential assistant to the physician, and the help of the skilled veterinary surgeon cannot be overlooked without serious danger to the public health. Is there, then, any prospect of the sanitary millennium, when infectious disease shall be no more? We must first have dealt satisfactorily with all disease germs without; we must be able to control entrances and exits; or we must have become able to confer racial immunity. Then, and not till then, will the plague be stayed. Ignorance is without doubt the mother of an untold amount of preventable disease. Such portions, therefore, of the sanitary domain as are matters of individual action should be made matters of primary education and be included in the curriculum of study by every boy and girl. How much longer shall such be taught the heights of mountains of no importance to them and parts of speech that are dead, but unfortunately not buried, and yet be left ignorant of the importance of heredity, the requirements of sound development, the dangers to health and how to avoid them, and similar every-day health factors? In addition, the creation of a sanitary atmosphere that will surround individuals and permeate households is a matter of scarcely less importance. To this end the initiation and combined activity of such bodies of earnest and trained sanitarians as constitute health societies, the St. John Ambulance Association, sanitary associations, and the like, become hygienic duties and privileges. With the spread of sanitary knowledge there is needed also a widening of the sphere of the physician's influence, for extended professional performance must accompany the broadening of public conception. The physician's usefulness must necessarily extend far beyond the remedial treatment of the sick. It will be more and more recognised that he is the trained servant of nature, able to do more preventatively than curatively, and more valuable by his advice than his drugs. Dealing with State sanitary control, he continued: "And since *Salus populi suprema lex*, it is not too much to say that the State which neglects to deal officially with these matters fails to perform one of its fundamental protective duties. To my mind the proper attitude to take up was well exemplified at the International Sanitary Exhibition just closed at Paris. In proposing the health of the President of the Republic the Dean of the Faculty of Medicine referred to faulty sanitation as a public danger and urged the passing of a Public Health Act. The President of the Cabinet Council, in reply held that it was the duty of the State to say to sanitarians, 'Show us what to do and we will do it.' And as an instance of a great community now prepared to act upon such expert advice I can refer you to the proposed sanitary reforms in India which seemed destined to create a new era in sanitation in that vast and densely populated peninsula. Enough has been said to show that the part that may be taken by our profession in the extension of knowledge, the creation of a sanitary atmosphere, the imparting of specific advice and administrative or scientific work, is a noble and inspiring one. And amidst all the drawbacks and disappointments which at times press so heavily upon us it is more than probable that, with Sir James Paget, we can claim for our calling from amongst all the sciences 'the most complete and constant union of those three qualities which have the greatest charm for pure and active minds—novelty, utility, and charity'; and that we can compete with the world, not where wealth is the highest evidence of success, but 'in the nobler ambition of being counted among the learned and the good, who strive to make the future better and happier than the past.' Thus it is granted us by our labours to promote the gradual approach of that sanitary millennium when heredity shall be counterbalanced, development progress harmoniously, external attack cease from troubling, and internal disquiet be at rest, until, in the fulness of time, there shall be left only that last enemy whose name is death. Then, were man only the perfection of the vital, the coping stone of the material, naught, 'tis true, would remain but the redistribution of atoms, the reincarnation of the vital, and the oblivion of personality. But such negation neither scientific leader nor scientific laureate finds himself compelled to accept. On Huxley's tomb is deeply graven the trust that survives a true agnosticism, and from Tennyson's grave still breathes the century's crowning message of hope and faith."

Mr. MASON (Otaki) introduced a discussion on Rural Hygiene, and Mr. A. G. KIDSTON-HUNTER read a paper on an Examination of Potable Water from Bacteriological and Chemical Points of View.

The Contagious Diseases Act.

This was the first subject taken in the Section, the memorial from the Women's Christian Temperance Union of Victoria having been referred to the Section with a view to discussion.

On the motion of Dr. KNAGGS (Sydney) the following resolution was carried unanimously: "That the question of the Contagious Diseases Act be referred to the next congress for discussion."

The PRESIDENT intimated that it was proposed to ask Mr. Grace to introduce the subject of the Contagious Diseases Act, and the section could then deal with it in some shape or form. His own opinion was that they would not be able to agree on the subject.

Mr. H. A. DE LAUTOUR (Oamaru) contributed papers on the Distinction between the Appearance of Razors, &c., in cases of Homicide and Suicide, and on a Simple Method of fixing and preserving Imprints of Foot or Finger-marks.

The Public Health Aspect of Alcohol.

Dr. CHAPPLE (Wellington) read a paper on the Public

Digitized by Google

Health Aspect of Alcohol. It was, he said, no part of the duty of medical men or medical societies as such to deal with the various ways suggested by social reformers and politicians of dealing with the liquor traffic. For the sake of their honour as a profession, however, and for the sake of their fellow men—accursed, diseased, and dying under the influence of alcohol—they could not afford to have done with the subject, however well worn it might be. For the sake of their honour as a profession—for nearly every popular belief in the efficacy and virtue of alcohol was false, and their high authority was claimed in support of the allegations that it increased the body heat, that it added strength and endurance to the muscles, that it was necessary to health, that it controlled hæmorrhage, that it was a disinfectant and protected from infection—and it was their duty to themselves and to the public to correct these beliefs, or at least to say that they had not their authority, for the sake of their fellow-men—for it was as much their duty to save them from the ravages of alcohol as from the ravages of cholera or any other preventable disease. He thus summarised his conclusions about alcohol taken as a beverage in health in varying quantities from physiological moderation to excess: (1) alcohol is a poisonous drug whose special action in the body is a brain cell paralysant, destroying these cells in the inverse order of their development; (2) alcohol disturbs the circulation, leading to a loss of body temperature and an accumulation of waste products in the blood, accompanied by great depression and muscular weakness; (3) alcohol tends to produce in all, proportionate to the quantity taken, cirrhotic diseases of all the tissues and organs of the body; (4) alcohol tends to produce an irresistible craving for itself; (5) alcohol predisposes to all infectious and many organic diseases; (6) alcohol diminishes the chances of recovery in those attacked by any diseases other than those resulting from its use; (7) alcohol increases the sick-rate and shortens life; (8) alcohol predisposes to phthisis and all tuberculous diseases; (9) alcohol increases lunacy and crime; (10) alcohol is absolutely unnecessary to health; (11) alcohol promotes hæmorrhage and does not check it; and (12) alcohol adds no muscular strength to the body—at most it encourages the expenditure of its force in the shortest possible time. If these were the true facts about alcohol taken as a beverage in health, they were as medical men, individually and collectively, in duty and in honour bound to make them known to the public.

Mr. SYMES (Christchurch) thought their efforts should not be so much directed towards preaching prohibition as towards reforming the system that existed. That reform would, he thought, have to be brought about in many ways. The beer supplied in the public-houses at the present day, particularly in the colonies, was not wholesome. The use of sugar and glucose in the manufacture of beer was most injurious to health. Some improvement might be made in the present system of supplying unwholesome and intoxicating beer.

Dr. OGSTON (Dunedin) could not agree with Dr. Chapple's statements with regard to the comparison between the abuse of alcohol and its moderate use. Alcohol was useful in small doses and harmful in big doses, but the same argument might be made to tell against tea.

Mr. SPRINGTHORPE said that as lecturer on Hygiene to the University of Melbourne he naturally had to go into this matter very carefully. It was a matter of great complexity, and although they all saw the evil effects of excess in the use of alcohol he did not think Dr. Chapple had gone deep enough down. The fact was that the human race in civilised parts was not absolutely and permanently healthy. Every race on the globe seemed more or less irresistibly drawn to a stimulo-sedative of some sort—if it was not alcohol it was some other stimulant. It was not merely a question of craving, it was an absolute instinct. They might prohibit a man's liquor and he would go in for stimulants in some other form. In Ireland they went in for ether drinking, and there were cocainists, morphinists, and all sorts of "'ists." He regarded it as a matter of the first importance to keep drink as much as possible from the young, to make its form as suitable as possible to the individual and his environments, and to see that a thoroughly sound article was obtained. This was, he thought, the direction in which legislation should tend.

Dr. STENHOUSE (Dunedin) said Dr. Chapple seemed to imagine that his case was true if he could show, on the one hand, that a moderate consumption of alcohol was not necessary to the health of the body, and if he could also show, on the other hand, that the consumption of alcohol in excess was detrimental to the body. But that was not sufficient, because if it could be shown that the moderate consumption of alcohol added somewhat to the pleasures of life, if it diffused happiness among mankind to some extent without being injurious, that was a great matter, seeing that we were not living in an ideal world and that the world was full of ups and downs, of anxieties and sorrows of one kind and another. He (Dr. Stenhouse) was sure, from his own observation, that the moderate and occasional use of alcohol was beneficial and that it enabled many a man to tide over a period of depression which otherwise might prove very disastrous. He had not the slightest doubt that the moderate consumption of alcohol after middle life was of considerable benefit and that it was advantageous to the prospects of longevity.

Mr. H. A. DE LAUTOUR (Oamaru) said that it was not his experience that alcohol-takers were more liable to typhoid fever than water-drinkers were, and he thought the statement was hardly reasonable, for they knew that typhoid fever was far more prevalent in children than in adults, and children were not drinkers.

Mr. MASON (Otaki) said that he enjoyed a glass of beer and thought it did him good, and he had no doubt that it was only when alcohol was taken in excess that the verdict could be given against it. Speaking from the physiological point of view, he thought there was no question that the teetotalers had "the best end of the stick."

Dr. MICKLE (Christchurch) had come to the conclusion in regard to alcoholic beverages that all healthy people did not require them and were better without them; but a very large minority of the population were undoubtedly benefited by their use. The reform he would like to see would be the establishment of a licence allowing the licensee to supply alcohol only as a beverage at meal times.

Hygiene as a School Subject.

The PRESIDENT moved: "That, in the opinion of this Congress, elementary hygiene should form a subject for instruction in all State-supported schools, and that where practicable teachers in such schools should be required to undergo a course of instruction in the same subject previously to their being licensed to teach."—The motion was carried.

Sanitary Administration.

The PRESIDENT also moved: "That this Congress respectfully beg to draw the attention of the different colonial Governments to the scheme by which the authorities of British India propose to deal with sanitary administration and the public health, with a view to the local adoption of a portion thereof as may be suitable to their respective requirements; and that they be respectfully asked to authorise a conference of their medical advisers empowered to report as to the best manner in which sanitary progress may be furthered."—The motion was carried.

Other Matters.

Papers by Dr. MULLINS on Death Certification and Registration in New South Wales and by Mr. MCDOUALL on Insanity from Association were received.

MIDWIFERY.

The address in the Section of Midwifery was read by Mr. MORIER, in the absence of Dr. WAY, the President of the Section. It dealt chiefly with the old maxim that "Cleanliness is next to godliness" and the bearing of the adage on puerperal fever.

Papers were read on Puerperal Eclampsia, with Special Reference to Urea Excretion, by Dr. W. W. R. LOVE, of Brisbane; and on a New Clamp, designed on an entirely new principle, for securing the broad ligament in vaginal hysterectomy, by Mr. J. H. TOWNEND of Christchurch.

GENERAL MEETING.

THE DISCUSSION ON TUBERCULOSIS.

The meetings of the various Sections were suspended in the forenoon of Wednesday, Feb. 5th, to enable a general meeting of members of the Congress to enter fully into the discussion of the principal topic set apart for the Congress—viz., Tuberculosis in Man and Animals.

Professor WATSON (Adelaide) opened the discussion and pointed out that it was meant to awaken the public

Digitized by Google

to the fact that tuberculosis is an infectious and therefore preventable and (under favourable circumstances) a curable disease. Living as they did in colonies where pastoral interests are paramount they had been wise in calling in to their assistance their best allies—the veterinary surgeons—men who had had ample opportunities of becoming conversant with the diversified manifestations of tuberculosis occurring in the domestic animals. It had been said that tuberculosis is Nature's method of working off the weak—a disease of degenerate tissues in a degenerate race. Tubercalisation of an individual did not appear to confer immunity in the same way as an infectious fever, such as small-pox, after it had run its course appeared to do. As regards South Australia, apart from alcohol, hydatids, and syphilis, the rapid extinction of the native race was due entirely to tuberculosis.

Mr. SPRINGTHORPE dealt with the more strictly medical aspects of the disease. He said: A disease like tuberculous disease—which, according to Hirschberger, kills one-fourth of all children dying under one year old; is responsible, according to Ransome, for one-half of all deaths during marriageable ages; is common, according to M'Lachlan and others, among the aged; and causes in all some 16 per cent. of the total mortality in civilised lands—merits special attention at a medical congress. Nor have we in Australasia any relative immunity from this universal scourge. Dr. M'Laurin's statistics show that it is the greatest single cause of death throughout Australasia, and that it is already as common in our large cities as in their European compeers. Our peculiarities, as Dr. Colquhoun, Dr. Corswell, and others have shown, are simply its comparative rarity in the young and frequency in the aged, and its later and slower affection of the middle-aged. It represents a great advance to be able to maintain that the disease is not possible in the absence of the tubercle bacillus. Gradually we are becoming acquainted with the life-history of this extraordinary germ. We have long known that it resists freezing, boiling, and putrefying, and have lately recognised that it is not an essential parasite in warm-blooded animals, but, under favourable circumstances, may pass a saprophytic existence in polluted environment. As to its frequency in man, the appalling death record may be taken as an incomplete illustration. Equally suggestive is its prevalence amongst the bovines. German and English statistics show a tuberculous infection of from 15 to 20 per cent. of the cattle slaughtered, and such Australian records as are available prove that our stock are affected in at least equal proportion. And as regards the extent of intermediate contamination of dwellings, buildings, conveyances, subsoil, &c., we have sufficient cause in the myriads of bacilli coughed up daily with tuberculous sputum, estimated at the Johns Hopkins University at hundreds and thousands of millions per patient, some no doubt dead, as Pfeiffer has shown, but many still living and virulent. The actual result is seen in the prevalence of the disease wherever people congregate together and take no care of the infected sputum. Unfortunately, in most cases, at least of advanced phthisis, the infection is not simple, but mixed. Antecedently to tuberculous infection frequently comes invasion by the influenza bacillus—the pneumococcus—the systemic weakness produced by zymotic and other diseases, and side by side with the tubercle bacillus itself are found a large variety of pyococci who now find a suitable nidus for their growth. It is to these indeed that, following good authorities as well as recording my own experience and opinion, I venture to think are to be attributed most of the septic phenomena which cast such a cloud over advancing phthisis—e.g., the hectic fever, the emaciation, the sweats, the profuse sputum, the "streptococcus curve," &c. And the recognition of this mixed infection is not only valuable pathologically—it is essential to a satisfactory therapeusis. Next to its recognition the important point regarding the bacillary factor in tuberculous disease is the understanding of the means of entrance and of exit. It is beyond question that environment may be polluted by tuberculous discharges, and that one serious source of tuberculous invasion lies in such polluted environment. Air and earth thus polluted are certainly frequent and extensive agents in the spread of tuberculous disease. Stop this avenue of invasion, and how much subsequent disease might not be prevented. Equally, if not more, important is the great question of tuberculous meat and milk. As regards dairy stock, statistics prove that it is far more common amongst aged milkers than in other classes of stock, with a greater tendency also to generalisation and thus to transmission through meat and milk. Systematic and skilled inspection of the food and milk supply thus stand out as among the most important of the hygienic functions of a government. It is to the credit of English medicine that it has persistently advocated the second factor in tuberculous disease—the constitutional weakness, itself a disease, upon which depends not only successful invasion, but rate and extent of spread. For the healthy human being possesses a resisting power which renders him practically immune against the bacillus so long as he remains healthy and though the disease cannot start without the bacillus, it cannot spread without the susceptibility. For the full understanding of the tuberculous question the English constitutional factor is as essential as the Continental germ factor. We require the union of the two. But whatever its inherent nature we find chemically that it varies wonderfully in degree and that the practical difficulty is to discover in what part of the scale the individual case is to be placed, a difficulty which is often insuperable, for there is absolutely no necessary relation between progress and extent. The fact is that the constitutional factor not only varies in different individuals, from nothing to infinity, but that it varies in the same individual according to the state of the constitutional health. Herein comes the value of the inflammatory origin of phthisis, once so much insisted upon; and hereon also hinges the possibility of reinfection at any subsequent time. The diagnosis of tuberculous disease is primarily bacillary and not histological. Yet how few physicians—I speak of English and Australian physicians, and am careful to exempt our Continental brethren—ever search for the bacillus or even make themselves competent to do so. Outside metropolitan hospitals it is the rare exception to find any such attempt made, and yet certainly a diagnosis, with all that depends thereon, is often only thus obtainable. The bacillary test, however, is defective. There may be no sputum, examination may give simply negative results, and the test itself gives no information as to the presence or extent of the constitutional factor. Hence it requires to be supplemented by clinical examination. Unfortunately neither constitutional weakness nor slight tuberculous infection is necessarily recognisable even by the most skilled clinician. Examination is often suggestive rather than conclusive, and this in the very cases where certainty is most desirable. Who, for example, has not met cases in which he found himself unable to be sure as to the tuberculous infection of fibroid phthisis, apical consolidation, apical pleural adhesion, pleural effusion, pleuro-pneumonia, chronic bronchitis, bronchitic asthma, or disease of bones, skin, &c.? As an invaluable aid in such diagnosis I venture strongly to recommend tuberculin. With Whittaker[1] I hold it established that a local reaction following injections of tuberculin is proof of the existence of tubercle at that point, and that a characteristic febrile reaction after injections of 0·005 or less may be taken as practical proof that tubercle is present somewhere in the system. After more than four years' continuous use of tuberculin I may perhaps claim to speak with some weight upon this point, and I venture to tell this Congress that I have always found tuberculin reliable diagnostically when used with discretion I place preventive treatment as incomparably before everything else. This includes the destruction of all approachable bacilli before their contamination of environment, the disinfection of infected environment, and the prevention of tuberculous infection through air, food, and milk. Some, at least, of these requirements demand State interference if they are to be satisfactorily performed; but it lies, in my opinion, at the door of our profession to do infinitely more than at present attempted. It is almost incredible—yet some years' continued inquiry have conclusively proved it to me—that scarcely a percentage of medical men give any instructions worthy the name for the destruction or disinfection of the sputum, and still less make any inquiry into the condition of the dairy from which the milk of their sick children is obtained, or direct that the unknown milk should be scalded before use. Who, again, pay attention to the killing of bacilli that must have collected in rooms and dwellings frequented by expectorating phthisical patients? And yet, in the absence of these essential precautions, we claim to be treating the case! And, worse still, we permit others—relatives, friends, and strangers—to run known risks of infection without word of warning or advice, with the frequent and unnecessary result of extension of infection

[1] Sajous' Annual of the Medical Sciences, 1892.

Digitized by Google

to those who were previously free therefrom. If, therefore, we are to sensibly lessen its ravages the first essential, in my opinion, is the more general recognition that the disease is to some extent infectious, and the spread of information as to the precautions which must be adopted if infection is to be prevented. I am one of those who believe in placing tuberculosis amongst the infectious diseases.

[Mr. Springthorpe here dealt at length with the subject of Tuberculosis, and concluded:]

As regards drugs, I think a lecturer on therapeutics has little to add. We all know the place filled by cod liver oil, hypophosphites, arsenic, quinine, strychnine, iron, the mineral acids, &c. Few probably will deny that we have no specific, that creosote and its allies are of value against sepsis rather than against the bacillus, and that the different symptoms which may arise during the course of the disease require from day to day as well as from year to year all the different combinations of remedies that the greatest experience and the wisest skill can suggest. Symptomatic treatment is not what we should aim at, but in a disease such as tuberculosis is at present it is often our only resort, and from the palliative point of view it is gratifying to know that we can so frequently relieve, even though cure is out of the question. But it would be impossible, even if it were appropriate, in such a paper as this to attempt any particularisation in such matters. Let me end where I began. It is by our preventive measures rather than by our remedial that we shall check this fell disease, which is so widespread that, according to Lord Playfair, it is the only one above the horizon from which we may anticipate the extinction of our race.

Mr. G. A. SYME (Melbourne) followed, addressing himself to the surgical aspects of tuberculosis.

Mr. A. PARK, M.R.C.V.S., exhibited a number of specimens of diseased portions of animals.

Mr. MURRAY-AYNSLEY (Christchurch) thought that they should make a firm protest against persons being sent out from the old country when they were seriously affected.

Mr. GARLAND (Oamaru) brought to the notice of the Congress the results of his treatment of cases with creosote, and advocated that this should be coupled with residence at high altitudes. Patients would often improve in such places without any treatment, and with the creosote treatment many cases would be very hopeful indeed.

Mr. S. S. CAMERON, M.R.C.V.S., said he did not think sufficient emphasis had been laid upon the universality of the disease in all species. The only domestic animals that were comparatively immune were the goat and the donkey. The great trouble in the past had been the want of opportunity for medical men to trace the source of tuberculosis. He took the opportunity of correcting the statement that tuberculosis could not be detected in cooked meat.

Dr. CHAPPLE (Wellington) said that four years ago, when spending a holiday on the west coast of the north island, he was asked to look at some young stock that had been bought for the purpose of being killed and examined. They were what were called "wasters," and doubt existed as to the cause of the disease. So virulent was this disease that whenever farmers noticed that cattle on good pasture began to waste they were sent to the stockyards for sale. An examination proved that the intestinal canal of these animals was studded with tuberculous ulcerations. That opinion was confirmed by Dr. Roberts, and when it became known within a fortnight fifty head of cattle were slaughtered. It was simply want of knowledge that caused the settlers to traffic in these animals, and as soon as it was really understood they were suffering from an infectious disease they were destroyed, and since then there had not been nearly so much tuberculous disease in that part of the colony.

Dr. KENNY (Melbourne) gave instances in his experience of the singular virtue of tuberculin as a diagnostic agent and of its value in treatment.

Dr. LOVE (Brisbane) advocated the public abattoir system, thorough inspection of meat offered for sale, and supervision of dairies. Canada and America were far ahead of the Australian colonies in this respect. In Canada (Ottawa, at any rate) the dairy cattle were subjected to periodical examination by means of tuberculin. In Denmark the authorities had instituted the tuberculin test, and this had been supplemented by a vote of £10,000 from the Government funds for the compensation of owners whose cattle were destroyed. The Central Board of Health in Sydney had instituted an examination on similar lines, and he understood paid 30*s.* a head for every beast which was condemned as tuberculous.

Dr. LINDO FERGUSON (Dunedin) submitted for inspection under the microscope tuberculous matter taken from the eye of one patient and the nose of another.

Dr. A. MARTIN (Wellington) suggested that strong representations should be made to the Government to discontinue the issue of New Zealand bank notes and to close up old clothes' shops. Remarks were also made by other members and

Mr. SPRINGTHORPE, in replying, said it seemed to be thought that because he had shown what the tubercle bacillus could do he wished to sound a pessimistic note. Nothing was further from his thought. He was one of those who believed that more people recovered from tuberculous diseases than ever died from them, but tuberculosis was the biggest disease the profession had to cope with. With regard to the question as to whether tuberculin introduced a reaction in other diseases, he replied that it was considered to be established by Professor Whittaker and others that a local reaction was proof positive of tuberculous disease. So far as he knew there had been no actual case where no tubercle was present, but they must remember there were cases of mixed affection. He thought a local reaction was proof positive, but he said nothing about a general reaction. Under the condition in which bacilli occurred in milk it was found that boiling did destroy most if not all. It was found that for practical purposes boiling or even scalding the milk had the effect of diminishing the number of the bacilli and of reducing their virulence, so that they did not get the result from boiled milk that they would get from unboiled.

Preventing Incurables from Emigrating.

Side by side with the main question there were some important observations on the advisability of taking steps to prevent advanced cases from being sent to the colonies.

Dr. TAYLOR YOUNG (Grafton, N.S.W.), as one of those to whom their professional brethren at home had recommended Australia, said that when he came out he learnt for himself which part of Australia to go to, and thought the profession should try to find out not only how to prevent disease, but how to prevent the wholesale "dumping down" of phthisical patients in Australia. As a Congress they would do good to suffering humanity if they offered a united front and endeavoured to insist on their Legislatures doing something to prevent the introduction of these patients to the colonies. He had seen proof of the introduction of these sufferers on his way across from New South Wales to New Zealand. He found the shipping companies indiscriminately classing together in close cabins dying phthisical patients and young people in whom there was no trace of the disease. On the *Manapouri*, coming from Sydney to Auckland there were three persons all of whom had come out in the same ship of the Orient line for the benefit of their health. He did not wish to dishearten them, but he thought to himself that the medical men at home must have desired to get rid of them. He hoped the Congress would do their best to put before the world the fact that Australia was not the place for these patients; he meant, of course, patients in the later stages of the disease. He was aware that Mr. Sydney Jones of New South Wales was now on the right lines for the early treatment of cases, and he believed that the endeavour to form model farms in the interior for such cases would result in many receiving benefit in the same way as he himself had done.

Dr. LOVE (Brisbane) observed that the death-rate from phthisis in Victoria and Queensland averaged from 12 to 14 per 10,000 per annum; in Great Britain it was about 16; and in New Zealand, which, he was happy to say, was low on the list, it was 6 to 8 per 10,000. If the general public at home were made aware of these figures they would be less inclined to send subjects out. They should also be made aware of the fact that cases of phthisis were now just as numerous among native-born colonists as among foreign-born.

Dr. MULHOLLAND (Melbourne) said it was not the practice at home for medical men to send cases of phthisis to the colonies. It was done on the advice of friends and not on the advice of medical men. He had attended the hospitals in Glasgow and in London, and in no instance had he heard medical men say to their patients that they should go to the colonies. He had heard them tell patients not to go.

The PRESIDENT remarked that there was one point which had struck him in the discussion. There was a certain interesting Bill which had exercised the minds of the people in this colony named the Undesirable Immigrants Bill. He

Digitized by Google

was not quite sure whether, if the Bill had been carried into law, they would have had the pleasure of seeing in New Zealand all who were present at the Congress; but it might be that after all there were some points in the Bill which would be of great value to the country.

The following motion was then carried unanimously:—"That a sub-committee be appointed, consisting of Dr. Ogton and Mr. Grace (of New Zealand), Professor Watson and Dr. Hamilton (of South Australia), Dr. Knaggs and Dr. Worrall (of New South Wales), Dr. Love (of Queensland), Professor Allen and Mr. Syme (of Victoria), with power to add to their number, to draw up and report to Congress for approval: (*a*) Printed slips of advice, suitable for general use by medical men in dealing with cases of phthisis; and (*b*) resolutions to be brought under the notice of the Governments of the different colonies, having as their object the general preventative measures deemed necessary for the prevention of the spread of tuberculous disease."

THE CLOSING MEETING OF THE CONGRESS.

The Next Congress.

The PRESIDENT (Dr. Batchelor) said the first business was the choice of the place of the next meeting of Congress. A letter had been received from the medical men of Brisbane inviting the Congress to meet in that city in 1899, and he moved that the invitation be accepted.

Dr. LOVE (Brisbane) supported the motion. The year 1899 had been proposed as the year of the next Congress and he would suggest that the time should be the winter. Brisbane had perhaps the finest climate in the world during the winter months, whereas the summer would, he feared, be found too hot for the comfort of visitors. Any month from May to October would do, and he should say that about July would be preferable. Fine weather could be pretty well depended on at that season.

The motion was carried unanimously.

Mr. GARDE (Brisbane) proposed that Dr. JOHN THOMSON of Brisbane be elected president.

The motion was carried *nem. con.*

Tuberculosis.

The sub-committee appointed to draw up resolutions recommended the approval of the following:—

"1. That this Congress expresses the opinion that it is unwise and cruel to recommend advanced cases of phthisis to seek Australasia as a health resort; that whilst there are many places in the different colonies of great climatic value in the earlier and curable stages the coastal regions generally are to be regarded as unsuited for almost all stages. (Copies of this resolution to be forwarded to the English medical press.) 2. That this Congress recommends for the use of medical men in their routine treatment of phthisis the printed table of advice and information originally drawn up by the Australian Health Society. 3. That recognising the serious extent to which tubercular disease prevails throughout Australasia, the fact that the disease is to some extent an infectious one, spreading through the medium of infected milk, meat, and air, this Congress begs respectfully to bring under the notice of the Governments of the different colonies the necessity which exists for the continuous and skilled inspection, veterinary as well as medical, of cattle and dairy stock of dairies, milk shops, and abattoirs; and for the proper disinfection of the public spittoons, conveyances, buildings, &c., known or suspected to have become infected. The Congress also strongly urges the general use of tuberculin as a test for the presence of tubercular disease in dairy and other stock."

Mr. SPRINGTHORPE moved the adoption of the resolutions. The sub-committee was representative of each colony and the resolutions were arrived at unanimously.

The motion was carried.

Testing the Vision.

The sub-section concerned with eye, ear, and throat diseases presented the following report:—

"1. That the Governments of the different colonies should take steps to ensure the proper testing of the vision of all men who are employed either at sea or in railway services whose duties are such that the lives of others depend on the acuteness of their sight either for form or colour.

"2. That all examinations of vision should be made by a properly qualified ophthalmic surgeon.

"3. That a high standard of vision and perfect colour sense should be insisted on for all men who are engaged as deck hands at sea and who have to undertake duty on the look-out or in steering. Also, that such a standard be fixed for those engaged in the engine-room as will suffice for their own safety and that of the ship.

"4. That a high standard be fixed for vision and perfect colour sense required in all deck officers of ships, that they be re-examined on each promotion, and after reaching the rank of master at intervals of five years.

"5. That the attention of the different Governments be called to the report of the Committee on Colour Vision presented to the Houses of Parliament in June, 1892, and to the report of the Council of the British Medical Association on the efficient control of railway servants' eyesight published in the same year, and that the standards recommended in these reports be taken as the basis on which the requirements of vision should be framed.

"6. That the attention of the different Governments be especially directed to the law passed in the State of Alabama in 1887 dealing with railway servants' eyesight, entitled 'An Act for the Protection of the Travelling Public against Accidents caused by Colour-blindness and Defective Vision,' as a model on which suitable legislation might be based.

"7. In order to put in a definite form the standard that should be aimed at the Congress suggests that no candidate be allowed to enter the dangerous services unless he is free from any chronic inflammation of the conjunctivæ or lids; he must be free from strabismus, and possess perfect equilibrium of the external ocular muscles; his distant vision must not be less than ⅚ in one eye and ⅚ with the other without glasses, the tests to be made with Snellen's types; he must have a perfect colour sense, tested both with Holmgren's wools and with distant colour tests under varying conditions; and he must also have a normal field of vision for both form and colour. Hypermetropia of more than one diopter should be a bar to entering the services."

Dr. LINDO FERGUSON (Dunedin) proposed the adoption of the resolutions. They were the result of a discussion, and it was thought that if they were adopted and forwarded to the various Governments they might pave the way to legislation which would lead to the greater safety of the travelling public. Some of the instances given during the discussion were enough to make one's hair stand on end.

The motion was carried.

The proceedings terminated with various complimentary votes of thanks to all who had taken part in what must be regarded on all sides as a most successful gathering.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the First Examination of the Board in the subjects indicated, under the "four years" regulations, at the April quarterly meeting of the Examiners, viz.,

Part I., Chemistry, including Chemical Physics:

Gould, Horace John, Middlesex Hospital.
Parlett, Frank, private study.

Part II., Materia Medica:

Abbott, Horatio White, Charing-cross Hospital.
Aldred, Fred Marsden, University College, Liverpool.
Beck, William, Aberdeen and Edinburgh Universities.
Beley, George, St. Thomas's Hospital.
Blackburn, Vernon Kent, Firth College, Sheffield.
Blackstone, Willoughby Arthur, University College, London
Campbell, Alfred, Sydney and Edinburgh Universities.
Cogswell, Philip Dare, St. Mary's Hospital.
Dunkin, Silas Ethelbert, Charing-cross Hospital.
Dury, George Kennion, Owens College, Manchester.
Dutton, William, Owens College, Manchester.
Foster, George Muir, University College, London.
Geach, Robert Neville, St. Bartholomew's Hospital.
Henchley, Albert Richard, Middlesex Hospital.
Millar, Alexander Fleming, St. Thomas's Hospital.
Moore, Eugene, Guy's Hospital.
Palmer, Charles John Linton, University College, Liverpool.
Preston, John Alexander, Queen's College, Belfast.
Provis, Cuthbert Howard Ralston, St. Bartholomew's Hospital.
Roberts, Harry Trist, Charing-cross Hospital.
Rooke, Frederick James Faulkland, Middlesex Hospital.
Salmon, Charles Arthur Craven, Guy's Hospital.
Stamford, Robert Basil, Guy's Hospital.
Treusch, John Benjamin August, Guy's Hospital.
Tucker, William Hancock, St. Thomas's Hospital.
Williams, Herbert Stephen Edgcumbe, St. Thomas's Hospital.
Wilson, Graham Lionel John, St. George's Hospital.
Worts, Charles Clifford, Guy's Hospital.
Young, Bertram Michell, St. Thomas's Hospital.

Part III., Elementary Physiology:

Alliott, Richard, Oxford University and St. Thomas's Hospital
Butler, Thomas Langton, St. Mary's Hospital.
Clemens, James Ross, St. Thomas's Hospital.
Duncan, John Marie Sloane Duncan, London Hospital.
Edwards, William Howard, Guy's Hospital.
Leathem, Alfred Newman, Charing-cross Hospital.
Molineux, Bernard Newmarch, St. Thomas's Hospital.
Nicholls, Ernest Albert, London Hospital.
Nicol, Burton Alexander, Charing-cross Hospital.
Pilcher, Cecil Westland, Oxford University.
Seville, George Edward, Owens College, Manchester.
Thompson, Arthur, St. Bartholomew's Hospital.
Widegren, Mathias Wilhelm Eberhard, St. Thomas's Hospital.

The following gentlemen passed the First Examination of the Board in the subjects indicated, under the "five years," regulations, at the April quarterly meeting of the examiners:—

Part I., Chemistry and Physics:

Ackery, Edward Faulkner, private study.
Adam, Thomas, Firth College, Sheffield.

Bartlett, Basil Sorley, St. Paul's School, West Kensington, and University College, London.
Bennett, Francis Grey, Cambridge University and University College, London.
Clark, Harold Gordon, University College, Bristol.
Cohen, Edward, Guy's Hospital.
Coke, William Fran is Harriott, St. George's Hospital.
Compton, Spencer Langley, University College, Bristol.
Coombes, Henry Reginald, Westminster Hospital.
Dixon, Godfrey Brookes, Charing-cross Hospital.
Donaldson, Samuel, St. Mary's Hospital.
Drabble, Charles Clement, Firth College, Sheffield.
Duprey, George Perry, Middlesex Hospital.
Fagan, Horace Charles John, St. Paul's School, West Kensington.
Fenton, Thomas Gerald, St Thomas's Hospital.
Forshaw, William Herbert, Firth College, Sheffield.
Foulds, Matthias Frederick, Owens College, Manchester.
Griffith, Richard, London Hospital.
Hardenberg, Emile John Frank, Guy's Hospital.
Hobbs, Albert Remington, St. Mary's Hospital.
Holroyd, Benjamin, Yorkshire College, Leeds.
Hoyle, John, Owens College, Manchester.
James, Herbert, Merchant Venturers School, Bristol.
Jaques, Robert, University College, Liverpool.
Jellicoe, Stanley Coleman, Middlesex Hospital.
Jones, Ernest Guy, Owens College, Manchester.
Kelly, Thomas Thelwell, Middlesex Hospital.
Kilpatrick, James Armstrong, University College of South Wales, Cardiff.
Kroenig, Victor Richard Fowell, King's College, London.
Lawson, James Ward, Charing-cross Hospital.
Leach, Herbert, Yorkshire College, Leeds.
Lister, Walter, Yorkshire College, Leeds.
Littlejohn, Edward Salterne, St. Paul's School, West Kensington.
Meadows, Sydney Manvers Woolner, Middlesex Hospital.
Nicholson, William, Owens College, Manchester.
Pitts, Arthur Gentry, Charing-cross Hospital.
Pooley, John Milnes, St. Mary's Hospital.
Potter, Godfrey Russell, Yorkshire College, Leeds.
Reardon, Arthur Francis, St. Thomas's Hospital.
Reid, Douglas Harold, Otago University and St. Thomas's Hospital.
Robinson, James Frederick, Birkbeck Institute and Guy's Hospital.
Rogers, Edward Norman Tilly, Middlesex Hospital.
Sayer, Thomas, Yorkshire College, Leeds.
Seager, Frank Randolph, Mason College, Birmingham.
Sly, Alfred Victor William, University College, London.
Sodenberg, John Emil, Westminster Hospital.
Staniforth, Henry Edward, Firth College, Sheffield.
Stevenson, Francis Daniel, St. George's Hospital.
Terry, Reginald Herbert, Guy's Hospital.
Thomson, Allen Bernard, King's College, London.
Vores, Cyril Preston, Westminster Hospital.
Wakefield, Walter, Mason College, Birmingham.
Wood, Maurice Dunbar, Guy's Hospital.
Wynne, Graham Shaw Arnold Smith, St. Bartholomew's Hospital.
Young, William John, University College, Liverpool.

Part II., Practical Pharmacy:

Anderson, William Monro, Charing-cross Hospital.
Bannerman, Walter Biggar, London Hospital.
Cazaly, William Henry, St. Bartholomew's Hospital.
Chaplin, Henry Ayrton, St. George's Hospital.
Cohen, Edward, Guy's Hospital.
Cory, Samuel Henry Gilbert, St. Mary's Hospital.
Cruise, Richard Robert, St. Mary's Hospital.
Douglass, Percy Clarence, St. Mary's Hospital.
Douse, Thomas Alexander, Charing-cross Hospital.
Evans, Frederick Hudson, King's College, London.
Fowler, Edwin Samuel George, Yorkshire College, Leeds.
Francis-Williams, Cecil Hughes, St. George's Hospital.
Graham, Allan Gordon, St. Thomas's Hospital.
Hammerton, George Herbert Leonard, Firth College, Sheffield.
Harrison, William Walter, Guy's Hospital.
Hughes, Robert, Owens College, Manchester.
Hunt, Albert William Dunning, Middlesex Hospital.
Jones, Richard Arthur, Charing-cross Hospital.
Kirkconnel, Edward Birchall, Owens College, Manchester.
Lewis, Arthur Daniel, Guy's Hospital.
Mossop, Charles Henry, Guy's Hospital.
Newham, Hugh Basil Greaves, St Thomas's Hospital.
Newling, Harry Tudor, St. Mary's Hospital.
Outred, Charles Deane, Guy's Hospital.
Pearson, Thomas, Charing-cross Hospital.
Powell, John Edward, Guy's Hospital.
Richardson, Walter Silverwood, Guy's Hospital.
Scott, Aleck Lauriston, St. Bartholomew's Hospital.
Skevington, Joseph Oliver, St. Mary's Hospital.
Smallwood, Matthew Edmund, University College, Liverpool.
Smith, Ernest George, St. Bartholomew's Hospital.
Smith, Malcolm Arthur, Charing-cross Hospital.
Symes, Ernest, University College, Bristol, and St. Mary's Hospital.
Walker, Herbert John, King's College, London.
Walton, Henry Beckles Gall, St. Mary's Hospital.
Watt, James George, Guy's Hospital.
Wingate, Basil Fenton, St. Mary's Hospital.
York, Thomas, Westminster Hospital.
Young, William John, University College, Liverpool.

Part III., Elementary Biology:

Adams, Ernest Beadon Dixon, St. Bartholomew's Hospital.
Adams, Henry Cyril, St. Bartholomew's Hospital.
Adam, Thomas, Firth College, Sheffield.
Alderman, Harry Cole, Yorkshire College, Leeds.
Anderson, William Monro, Charing-cross Hospital.
Arch, Arthur James, Mason College, Birmingham.
Ascough, Matthew Thomas, Owens College, Manchester.
Ashley, Herbert Ernest, St. Bartholomew's Hospital.
Attwood, Richard Denton, Guy's Hospital.
Awdry, Arthur John, Mason College, Birmingham.
Aylen, Ernest Vaughan, London Hospital.
Bagge, James Charles, St. Thomas's Hospital.
Barrett, Henry Edward, St. Mary's Hospital.
Bartlett, Charles Eastty, Guy's Hospital.
Bartlett, John Allen, University College, Bristol.
Beale-Browne, Thomas Richard, Guy's Hospital.
Bennett, Kenneth Hugh, University College, London.
Bishop, Frederick Michael, St. Bartholomew's Hospital.
Blizzard, Walter Harry Stanley, Mason College, Birmingham.
Body, Thomas Munn, St. Bartholomew's Hospital.
Bond, Cecil William, St. Mary's Hospital.
Bostock, Arthur Hastings, St. Bartholomew's Hospital.
Bramsbury, Henry Arthur Bramsdon, St. George's Hospital.
Breeze, Joseph Ernest, Mason College, Birmingham.
Broomhall, Benjamin Charles, London Hospital.
Burd, Reginald Shirley, Mason College, Birmingham.
Butler, Archibald, St. Bartholomew's Hospital.
Chalk, Charles Launder, St. Bartholomew's Hospital.
Challans, Frank, London Hospital.
Chaplin, Henry Ayrton, St. George's Hospital.
Clark, John Wilders Hambly, London Hospital.
Clarke, Arthur Allen Foster, St. Thomas's Hospital.
Coates, John, St. Thomas's Hospital.
Cohen, Edward, Guy's Hospital.
Coke, William Francis Harriott, St. George's Hospital.
Compton, Alwyne Theodore, St. Bartholomew's Hospital.
Cory, Harold Myrie, Mason College Birmingham.
Cox, George Ralph, St. Mary's Hospital.
Cross, Francis George, Guy's Hospital.
Cruickshank, Alex Douglas Macdonell, London Hospital.
Curtis, Frederick, Guy's Hospital.
Da Silva, Joseph Clement, Guy's Hospital.
Davey, James, London Hospital.
Davidson, William Henry, London Hospital.
De Carteret, Sylvester, St. Bartholomew's Hospital.
Donaldson-Sim, Ernest Alfred, St. Bartholomew's Hospital.
Downton, Arthur Sydney, London Hospital.
Duigan, Victor John, St. Bartholomew's Hospital.
Duncan, Emile Horace George, St. Bartholomew's Hospital.
Dunstan, Robert, London Hospital.
Edwards, Arthur Baynes, St. Bartholomew's Hospital.
Edwards, Thomas Henry, St. Thomas's Hospital.
Ellis, Frank Heygate, St. Bartholomew's Hospital.
Enderby, Thomas Sidney Dawber, St. Thomas's Hospital.
Faber, Hamilton Stanley, St George's Hospital.
Felton, Edgar Hall, Guy's Hospital.
Forrest, Frank, Owens College, Manchester.
Fort, Percy Reginald, St. Mary's Hospital.
Foster, Edward Cecil, University College, London.
Foulkes, Samuel Newall, London Hospital.
Furley, George Frederic, St. Bartholomew's Hospital.
Gaitskell, Charles Edward, Guy's Hospital.
Garle, Robert Hubert Williamson, St. Thomas's Hospital.
Garstang, Walter, Owens College, Manchester.
Gauntlett, Owen Binns, St. Thomas's Hospital.
Gilbert, Walter Raleigh, St. Thomas's Hospital.
Gill, Clifford Allchin, University College, London.
Gleig, Percy North, Charing-cross Hospital.
Goodair, Percy Hamilton, St. Thomas's Hospital.
Gould, Alexander Cyril, St. Mary's Hospital.
Graham, Cecil Irving, St. Mary's Hospital.
Greaves, Ernest Walters, St. George's Hospital.
Green, Arthur Llewellyn Baldwin, St. Bartholomew's Hospital.
Griffin, Gerald, London Hospital.
Grimshaw, Charles Richard Atkinson, St. Bartholomew's Hospital.
Hagger, Roger Lionel, University College, London.
Hanbury, Langton Fuller, St. Thomas's Hospital.
Hanbury, Reginald Janson, St. Bartholomew's Hospital.
Hardenberg, Emile John Frank, Guy's Hospital.
Hay, Malcolm Bell, University College, London.
Haydon, Maurice Willoughby, St. Thomas's Hospital.
Haydon, Walter Turner, St. Thomas's Hospital.
Hayne, Percy Alfred, St. George's Hospital.
Hepper, Evelyn Charles, St. Bartholomew's Hospital.
Hertslet, Lewis Eccles, London Hospital.
Heseltine, Verner George, St Bartholomew's Hospital.
Hingston, Clayton Alex. Francis, Middlesex Hospital.
Hollick, Bernard Septimus, Mason College, Birmingham.
Holroyd, Benjamin, Yorkshire College, Leeds.
Horsey, Frederick Samuel, St. Mary's Hospital.
Hosford, Alfred Stroud, University College, London.
Hoyle, John, Owens College, Manchester.
Hughes, Leslie Edward, St. Bartholomew's Hospital.
Humphreys, George Jacks, St. Bartholomew's Hospital.
Hutchinson, Thomas, Mason College, Birmingham.
Inness, William James Deacon, St Mary's Hospital.
James, Herbert, Merchant Venturers School, Bristol.
James, William Warwick, Middlesex Hospital.
Jaques, Robert, University College, Liverpool.
Jellicoe, Stanley Coleman, Middlesex Hospital.
Johanson, Edward Georg, Westminster Hospital.
Johnson, William Gerold Greaves, St. Bartholomew's Hospital.
Jones, Ernest Guy, Owens College, Manchester.
Jones, John Pugh, University College of South Wales.
Jupp, Ralph Tennyson, Mason College, Birmingham.
Keigwin, George John William, London Hospital.
Kempthorne, Hugh Dorset, Guy's Hospital.
Kirton, David Henry, Mason College, Birmingham.
Kroening, Victor Richard Fowell, King's College, London.
Leach, Herbert, Yorkshire College, Leeds.
Leah, Frederick Arthur, Owens College, Manchester.
Leonard, Napoleon, St. Bartholomew's Hospital.
Lewis, William Spencer, Owens College, Manchester.
Lipscomb, Neil, St. Bartholomew's Hospital.
Lloyd, Robert Archer, St. Bartholomew's Hospital.
McBride, Charles Gordon, St. Thomas's Hospital.
Maitland, Vivian Gray, Mason College, Birmingham.
Marsh, Charles Alfred, London Hospital.
Marrett, Henry Norman, St. Bartholomew's Hospital.

Mead, Edgar Preston, London Hospital.
Meadows, Sydney Nanvers Woolner, Middlesex Hospital.
Mence, William Charles, St. Thomas's Hospital.
Miles, Thomas George, Guy's Hospital.
Miles, William Percival, St. Bartholomew's Hospital.
Mitchell, Talbot Carter, Yorkshire College, Leeds.
Morcom, Theophilus William, London Hospital.
Moore, Leonard Augustine, University College, Bristol.
Muter, Charles William, King's College, London.
Newport, Harry MacGregor, Charing-cross Hospital.
Nicholson, William, Owens College, Manchester.
Norton, John Chalmers, University College, Bristol.
Oades, Geoffrey Smyth, Merchant Venturers School, Bristol.
Paget, Walter Gray, St. Bartholomew's Hospital.
Palmer, Charles Ambrose, St. Thomas's Hospital.
Parker, Christian, London Hospital.
Parker, Herbert Alban, St. Thomas's Hospital.
Pascoe, James Sydney, Charing-cross Hospital.
Peake, Sydney John, King's College, London.
Perkins, Eric McLeod, London Hospital.
Perkins, Philip Meyler, St. Bartholomew's Hospital.
Pern, Lionel, Guy's Hospital.
Petty, James Bertie, Charing-cross Hospital.
Pollock, Aubrey Kearinge Halliday, St. Bartholomew's Hospital.
Porter, Charles Robertson, London Hospital.
Potter, Godfrey Russell, Yorkshire College, Leeds.
Reid, Douglas Harold, St. Thomas's Hospital.
Reilly, Percy George, London Hospital.
Renshaw, William Cooke, Owens College, Manchester.
Rice, Frank Melville Pitcairn, St. Bartholomew's Hospital.
Richards, Ralph Conrad, University College, London.
Ridge, Edwyn Manners, London Hospital.
Roberts, Thomas Howard Frederick, Guy's Hospital.
Robertson, James Fenwick, St. Bartholomew's Hospital.
Rogers, Edward Norman Tilly, Middlesex Hospital.
Saunders, Leonard Douglas, St. George's Hospital.
Sayer, Thomas, Yorkshire College, Leeds.
Serpell, Hugh Hamilton, St. Bartholomew's Hospital.
Seagrove, George Mervyn, St. Bartholomew's Hospital.
Sich, Hugh Hamilton, St. George's Hospital.
Sime, Frank Wheler, Guy's Hospital.
Skelton, Dudley Sheridan, London Hospital.
Smale, Herbert, St. Mary's Hospital.
Small, Robert, St. Thomas's Hospital.
Smith, Ernest George, St. Bartholomew's Hospital.
Smith, George Percy, Mason College, Birmingham.
Smith, Robert Howard Newby, London Hospital.
Sodhi, Makham Singh, London Hospital.
Soper, Gerald Morgan, St. Mary's Hospital.
Spitta, Harold Robert Dacre, St. George's Hospital,
Staniforth, Henry Edward, Firth College, Sheffield.
Steele, William Lawrence, University College, London.
Steen, Wilfred Alexander, London Hospital.
Swindale, Henry Vernon, Middlesex Hospital.
Symons, Angelo Nelson, London Hospital.
Tayler, Frederick Ernest, St. Bartholomew's Hospital.
Terry, Reginald Herbert, Guy's Hospital.
Thomson, Frederic William, Firth College, Sheffield.
Thorne, Richard Thorne, St. Bartholomew's Hospital.
Tilbury, Robert, Guy's Hospital.
Tovey, Arthur Hamilton, St. George's Hospital.
Tordiffe, Arthur Murray Stewart, University College, Bristol.
Turle, James Evan, University College, London.
Turner, Douglas Duke, St. Thomas's Hospital.
Tweedie, Alexander Robert, St. Bartholomew's Hospital.
Upcott Gill, Geoffrey Allen, University College, London.
Wadmore, James Christopher, University College, Bristol.
Walker, Ernest, Charing-cross Hospital.
Walker, Frederick George, St. George's Hospital.
Wallis, Vernon Montague, Guy's Hospital.
Walters, Charles Ferrier, University College, Bristol.
Walters, Joseph, University College of South Wales, Cardiff.
Webb, Louis, Guy's Hospital.
Welch, Frederick Day, London Hospital.
Wellington, Arthur Robartes, St. Mary's Hospital.
Whitaker, Roy Henry Rollinson, St. Bartholomew's Hospital.
Willett, Edward Lightfoot, Owens College, Manchester.
Willey, Frederick, Yorkshire College, Leeds.
Williams, Arthur Harold, London Hospital.
Wilson, Frederick Ernest, University College, London, and Guy's Hospital.
Wilson, Richard Eldred, London Hospital.
Winder, Maurice Guy, St. Bartholomew's Hospital.
Young, Thomas, St. Bartholomew's Hospital.
Young, William John, University College, Liverpool.

SOCIETY OF APOTHECARIES OF LONDON, APRIL, 1896.—The following candidates passed in the undermentioned subjects:—

Surgery.—H. L. Billett, E. L. Colebrook, Royal Free Hospital; F. C. B. Gittings, Middlesex Hospital; W. A. Harmer, Aberdeen; C. G. Higginson, A. Hilton, Manchester; E. C. Hort, Cambridge and Guy's Hospital; C. E. Long, Royal Free Hospital; A. V. Moreton, Manchester; A. T. Morgan, Bristol; and S. F. Smith, St. George's Hospital.

Medicine, Forensic Medicine, and Midwifery.—E. C. Bond, A. M. Browne, E. L. Colebrook, Royal Free Hospital; L. F. Forbes-Winslow, Charing-cross Hospital; F. C. B. Gittings, Middlesex Hospital; and C. E. Long, Royal Free Hospital.

Medicine and Forensic Medicine.—C. A. K. Renshaw, Cambridge and Manchester; and W. L. Roberts, St. Mary's Hospital.

Medicine and Midwifery.—T. B. Bokenham, St. Bartholomew's Hospital; and M. Orange, Royal Free Hospital.

Medicine.—A. N. Clemenger, St. George's Hospital; and T. G. King, London Hospital.

Forensic Medicine and Midwifery.—W. A. Davidson, Birmingham and London; R. N. De Beauvais, Aberdeen and St. Mary's Hospital; H. Herbert, London Hospital; and C. N. Saldanha, Madras.

Forensic Medicine.—F. C. Collinson, Leeds; F. R. M. Heggs, Birmingham; and A. W. Shea, Dublin and Sheffield.

Midwifery.—H. L. Billett, Royal Free Hospital; and C. A. A. Coulthard, St. George's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—E. C. Bond, E. L. Colebrook, F. C. Collinson, L. F. Forbes-Winslow, F. C. B. Gittings, W. A. Harmer, A. Hilton, E. C. Hort, C. E. Long, and A. T. Morgan.

LITERARY INTELLIGENCE.—Messrs. Frank Weir and Co., of New York, announce the first number of a monthly periodical, which will contain in the form of a classified subject-index the titles of all papers that have appeared during the previous month in the medical journals of the United States and Canada and in the published Transactions of the various medical societies of these countries.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 15th, Dr. Mutch, President, being in the chair.—Mr. Laws read a paper on Colour Vision, illustrated by pendulum apparatus and colour-top, of which an abstract will be found on p. 1125.—Dr. W. B. Ransom showed the Reaction to Iodine of several specimens of Gluten Flour from well-known manufacturers. All the specimens contained a considerable amount of starch except one of Soya flour.—Dr. Hunter showed a Stomach containing two Perforated Ulcers from the body of a young woman who had died after a short attack of acute abdominal pain. He also showed Enlarged Mesenteric Glands, presumably tuberculous, from a child two months old.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The seventh meeting of the session was held on April 8th in the Medical Library of University College, Bristol.—Dr. P. W. Williams mentioned that the Huxley Memorial Fund was now started and that he would be glad to receive subscriptions to the same.—Dr. P. W. Williams showed a patient with Cerebral Spastic Diplegia and a patient with Early Intrinsic Malignant Disease of the Larynx.—Mr. J. Swain made some remarks on the second patient.—Mr. F. W. Crossman (for Dr. Crossman) showed a specimen of Perforation of the Duodenum.—Mr. T. Carwardine read an interesting paper on Dermoid of the Neck.—Mr. Munro Smith, Mr. J. Swain, and Dr. Edgeworth commented on the paper.—Mr. Paul Bush read a paper on a case of Compression of the Brain due to Rupture of the Middle Meningeal Artery which he had treated by operation and which ended in complete recovery.—Dr. Michell Clarke remarked on the paper.—Mr. Munro Smith gave a Lantern Demonstration of Photographs by "x" Rays; and also of cases of Chancres on the Fingers, &c.—Dr. Shingleton Smith and Mr. James Taylor gave a Lantern Demonstration of some of the ordinary Human Parasites.—Dr. Michell Clarke and Mr. James Taylor gave a Lantern Demonstration of the Nerve Cells and Fibres stained by Golgi's method.

DIPHTHERIA IN LONDON.—The data for the third period of four weeks of the present year are now before us with regard to diphtheria in London. They are not very encouraging. It would appear that in the four weeks ended on March 21st the notifications of the disease in the metropolis amounted to a total of 1009, or an average of 252 weekly, and that all but two of the sanitary areas of the county of London were invaded. Camberwell had as many as 119 notified cases, and the four districts which had upwards of 50 notifications accounted for a total of 304, or 30 per cent. of the 41 invaded areas. The corresponding period of 1895 saw only 488 notifications, and the two preceding monthly periods of this current year 988 and 1054 respectively. The registered deaths in the period ended on March 21st were 191, or 48 weekly, and were at the rate of nearly 19 per cent. of the notified cases. Since the close of this period—i.e., since March 21st—the weekly deaths have been 51, 45, 45, and 42 respectively. The average has thus been 46, a slight decline on that of the preceding four weeks. Last week the admissions to hospital were 90, against 105, 82, and 78 in the preceding three weeks. The patients remaining in hospital on Saturday last numbered 671, as compared with 712 and 706 on the corresponding Saturdays of February and March. In the last three weeks the registered deaths from diphtheria in the West Ham district have been as many as 6, 8, and 10, this suburb of London remaining in an unenviable position.

MESSRS. ALLEN AND HANBURYS have installed at 48, Wigmore-street, Cavendish-square, a complete apparatus for the demonstration of the new mode of photography.

PRESENTATION TO A MEDICAL MAN.—At the Plymouth terminus of the London and South Western Railway on the occasion of presenting, on Saturday last, certificates to the successful members of the Friary Ambulance Class, Dr. Wm. A. Buchan of Plymouth was the recipient of an engraved silver cigarette case for his instructive lectures on First Aid.

NORTH-WEST LONDON CLINICAL SOCIETY.—A clinical meeting of this society was held on April 15th. Dr. Harry Campbell showed two cases of Hemiplegia, both in middle-aged women. The first case was a typical example of cerebral hæmorrhage. Consciousness had been lost and left-sided hemiplegia rapidly developed. In this case almost complete recovery had taken place. The second patient had suffered from dilated heart, and paresis followed by paralysis of the right arm ensued. The arm had remained absolutely powerless. Dr. Campbell regarded the second case as one of arterial thrombosis.—Dr. Sibley showed a case of Psoriasis in a girl. The case had done well under oil of cade locally and arsenic internally. The lesions were abundant on the scalp and trunk, but there were none upon the elbows or knees.—Mr. Jackson Clarke showed a case of Raynaud's Disease in a woman aged thirty-five. There was a sloughy ulcer on the middle finger of the left hand. Mr. Clarke also showed an elderly woman who had suffered from Osteo-arthritis for thirty-three years. Nearly all the larger joints and the temporo-maxillary articulations were affected. The elbow joints were greatly enlarged and the tense fluctuating swellings showed that not only was the capsule distended, but that there were hernial protrusions of the synovial membrane beyond the capsule.—Dr. Sibley showed an unmarried woman aged twenty-eight with a large firm tumour occupying the lower half of the abdomen. The patient had suffered no inconvenience beyond discomfort caused by the weight of the growth. Menstruation had not been disturbed. Dr. Sibley believed it to be a large solid tumour of the left ovary.

THE DIFFUSION OF SMALL-POX.—Only one death from small-pox was registered last week among the thirty-three large towns dealt with by the Registrar-General; this was at Leeds. No death has occurred in London since the two registered in the week ending March 7th. The notified cases during the four weeks ending March 21st numbered only 23, and of these 9 belonged to Islington, 5 to Hackney, and 4 to Lambeth. In the preceding four weeks the total notified cases in London had been exactly double this number. At Gloucester matters have not improved. The Sanitary Committee reported up to Thursday of last week a total of 1302 cases in the city. In the week ended on that day the fresh cases had been 201, the deaths in hospital 25, and outside the institution 20, leaving in hospital 248 patients. The discharges in the week numbered only 18. These figures are not hopeful. The epidemic has now reached parts of the city hitherto free, the courts, slums, and alleys being invaded. The Town Clerk has written a strong letter to the Press on the present attitude of the authorities local and central towards the vaccination question, pointing out that prior to any move made at Gloucester either on the part of the central board, or of the local board of guardians, the corporation had got the machinery for securing the vaccination of the city into operation. He denies the efficacy of the staff provided by the guardians, even under pressure, to cope with the heavy arrears of unvaccinated persons. The fall in the numbers of new cases in the three days which ended on Monday of last week has not been maintained. The attacks reported on Tuesday increased to 51, although this number included some cases which occurred on the Monday. It would appear that much complaint has been made as to the haphazard manner in which isolated families have been visited with the view of ascertaining whether any members had sickened in consequence of the primary invasion of the household. Some families are stated to have been left unvisited for four weeks together with only one week's pay. As a consequence of this neglect members of their households had been out mixing with the general public. Instances of gross carelessness have been reported, such as the visiting of the homes of persons where those dead of small-pox were lying and the crowding around patients by their neighbours in the foolish though natural desire of saying good-bye prior to removal to hospital. A man with the disease out upon him has been discovered in a public thoroughfare, and another patient escaped from his residence and was only captured after being some hours at large. These are but instances of the difficulties with which the sanitary officials have to contend. In addition, failures to notify cases have been met with. In the case of one family, thirty attacks have been traced to concealed occurrences in the house. Meantime, vaccination and revaccination proceed, and in the week ended April 18th the persons vaccinated by the public vaccinators numbered 3285, while the work of private practitioners probably brings the total up to nearly 4000. Upon the direct representation of the corporation the guardians have acquiesced in the proposal that they should appoint additional vaccinators for the purpose of more quickly securing the protection of the unvaccinated who are still very numerous in the city. The corporation have done a good work by carrying on a house-to-house visitation for the same purpose. The Local Government Board, at the special request of the guardians, dispatched Dr. Sweeting to Gloucester on Wednesday and thus once again showed their practical desire to aid the local bodies in their efforts to defend the town against further inroads of small-pox. Dr. Coupland, on behalf of the Royal Commission on Vaccination, has again visited the city and has proceeded further with his detailed investigation of the circumstances of the outbreak in so far as they may have interest for the Commission. A Mr. Pickering has announced his ability to treat successfully all cases of small-pox by a hydropathic method and a local chapel was actually placed at his disposal as a temporary hospital for the treatment of those severer cases which could not be treated in their homes; but the hostile attitude of the citizens, provoked rather by the aggregation of small-pox cases in a populous neighbourhood than by any inherent distrust in Mr. Pickering's folly, has interfered with the smoothness of that gentleman's proceedings. Social events continue to be postponed, and the Bishop of Gloucester has requested candidates for holy orders coming up to the postponed ordination to be revaccinated before entering the city. Funds still flow in for the nursing of poorer patients, and charity in other forms is cheerfully sent in to the authorities. The grand jury of the Easter quarter sessions of the peace at Gloucester have made a presentment strongly in favour of the necessity of vaccination at the present juncture, and have expressed their belief that the duty of administering the Vaccination Acts should be withdrawn from guardians and placed in the hands of the Local Government Board or some other independent body.

Parliamentary Intelligence.

CURRENT NOTES.

The Budget.

THE Chancellor of the Exchequer (Sir Michael Hicks-Beach) made his Budget statement on Thursday, April 16th, and in the course of it gave some interesting information as to the changes in the popular taste in the matter of drink of one kind and another. For instance, he said that whereas in the year 1875 the consumption of cocoa was 5 oz. per head of the population, double that amount was consumed last year, while in the matter of coffee against 21 oz. per head consumed forty years ago there was last year only 11 oz. per head. Tea, he said, is driving coffee out of the market "because it is cheaper, because it requires less milk and because it is easier for people to make." With regard to spirituous drink, he was able to assure the House that British and Irish spirits are entirely displacing foreign spirits, that since the year 1870 the consumption of the latter has declined 23 per cent., while the consumption of the former has increased by 5 per cent. The taste for rum, except in the most extraordinarily cold weather, would appear to be declining in England, and the explanation given was that "people prefer, as they do in wine, what I may call a lighter and cleaner spirit." The figures with regard to tea show an increased consumption during the year of no less than 10,000,000 pounds weight, and point to the trade being rapidly transferred from China to India and Ceylon. In 1875 more than 122,000,000 lb. came from China, and in 1895 only 31,500,000 lb., while as to India and Ceylon there came from these countries in 1875 23,220,000 lb., and in 1895 190,500,000 lb. With regard to tobacco, Sir Michael Hicks-Beach said there has been a great increase in the consumption of cigarettes, largely due, as he suggested, to the taste

Digitized by Google

of youths in this direction, and with regard to wines he said that the stronger kinds are decreasing, while the lighter sorts are increasing in popularity. As to the Budget proposals, it is perhaps enough to say here that they do not include any increase in taxation.

Mining Accidents.

The Government has introduced in the House of Commons a Bill to amend the Coal Mines Regulation Act of 1887 in the direction of increasing the precautions against accidents in fiery and dusty mines.

The Vaccination Commission.

Mr. Chaplin, President of the Local Government Board, has made it known that he has availed himself, and intends to continue to avail himself, of every opportunity presenting itself of informing boards of guardians that they have no legal right whatever to suspend action for the enforcement of the vaccination laws pending the issue of the report of the Royal Commission.

HOUSE OF COMMONS.

THURSDAY, APRIL 16TH.

Treatment of Inebriates.

Mr. Knowles asked the Secretary of State for the Home Department if he would introduce at an early date a Bill to carry out the report from the Departmental Committee on the treatment of inebriates.—Sir Matthew White Ridley replied: The Bill is in draft, but I am afraid I cannot say when I shall be able to introduce it. The establishment of inebriates' reformatories and the detention in them for long periods of persons habitually convicted of drunkenness are, as the hon. member is aware, an entirely new departure in our methods of dealing with crime, and the details of the measure, especially from a financial point of view, require the most careful consideration.

Poor-law Schools.

Mr. Chaplin, in reply to a question by Mr. Bemrose, said the Local Government Board were aware that considerable numbers of children had been retained of late in London workhouses for want of school accommodation and for other reasons, and that the arrangements where they were so retained were not in all cases satisfactory. Questions as regards school accommodation for Poor-law children had necessarily been much in abeyance pending the inquiry of the Poor-law Schools Committee.

Cycle Accidents in London.

Sir Matthew White Ridley, replying to several questions on this subject, said: I have obtained a return which has been prepared by the police after careful inquiry, showing the number of fatal and serious accidents which have occurred to cyclists in the police district during the first quarter of the year. The number of fatal accidents was three; of serious accidents, such as fracture of limb, concussion, internal injuries, 12; in two cases only were the persons injured women. There have been, besides, numerous cases of slight accidents in which persons have either gone to their homes or, if taken to the hospital, have not been detained there. Considering the great number of those who ride in the streets, I cannot say that these figures are high or call for any exceptional measures. At the same time, there can be no doubt there is a great deal of reckless riding; during the first quarter of the year 318 persons were summoned by the police for this and similar offences. I have no power, however, to limit cyclists to certain thoroughfares or to subject them to regulations not applicable to traffic generally; but the police do everything in their power to minimise risk. In only one case, so far as I have been able to ascertain, has a coroner recently made any remark on the subject of these accidents in the London streets.

FRIDAY, APRIL 17TH.

The Fees of Medical Witnesses.

Dr. Farquharson asked the Secretary of State for the Home Department whether his attention had been called to the serious loss of time and money incurred by medical witnesses, who were compelled to leave their practices in order to give evidence at sessions and assizes in England and Wales, for which no adequate remuneration was given them, and, if so, whether he was prepared to provide a remedy by assimilating the fees to those paid in Scotland.—Sir Matthew White Ridley replied: The question of the remuneration of medical witnesses has received the consideration both of my predecessor and myself. It forms a part only of the question of the remuneration of witnesses generally, and I should not feel justified in altering the amounts to be paid to one class of witnesses alone. I am disposed to think that the revision of the present general scale, which was fixed so long ago as 1858, will require to be undertaken sooner or later, but any such general alteration would be attended by a large increase of expenditure falling on county funds.

MONDAY, APRIL 20TH.

Pleuro-pneumonia.

Mr. White asked the President of the Board of Agriculture whether, as in the case of swine fever, he would appoint a departmental committee to review the experience gained since (say) 1890 respecting the etiology, pathology, and morbid anatomy of the diseases known as pleuro-pneumonia; to supplement that experience by a series of experiments as to the bacteriology and life history of these diseases, and as to their communication, either directly or indirectly, from animal to animal; and to bring together the results of the work of foreign investigators.—Mr. Walter Long replied: Our scientific knowledge respecting pleuro-pneumonia is much more extensive than in the case of swine fever, and I have no reason to believe that it would be materially increased by the appointment of a departmental committee, whose opportunities for investigation would be very small by reason of the fact that cases of the disease in this country are happily now so rare. In these circumstances I do not see my way to adopt the suggestion of the hon. member.

The Disinfecting of Clothing.

Mr. Young asked the Chief Secretary to the Lord-Lieutenant of Ireland whether he was aware that the rule which compelled all sick persons, whether pay patients or not, entering the infirmary of a workhouse to wear union clothes prevented large numbers from availing themselves of those hospitals, thereby causing much suffering and the spread of infectious diseases, especially in rural districts; and whether he would take steps to rescind this rule and leave it discretionary with the medical officers to permit patients to use their own clothes when considered by them sanitary.—Mr. Gerald Balfour replied that the rule referred to, which also applied in England and Scotland, required that the clothing of patients suffering from infectious and other diseases should be taken from them on admission to the workhouse infirmary and cleansed and disinfected. He was not aware that the operation of this rule had the effect ascribed to it in the question, and the Local Government Board were of opinion that it could not be rescinded without endangering the health of the inmates of the institution; nor was it deemed advisable to vest in the medical officer the discretionary power suggested.

TUESDAY, APRIL 21ST.

The Tuberculosis Commission.

Mr. Cawley asked the President of the Local Government Board whether, in view of the fact brought to light by the Royal Commission on Tuberculosis that so many cows suffering from tuberculosis were giving milk which was supplied to consumers, and that the milk from these cows was dangerous to the health of human beings, he was prepared to institute some system by which all cows whose milk was sold for public consumption should be placed under compulsory inspection.—Mr. Chaplin said in reply: While the report of the Commission of 1895 has dealt fully with the scientific aspects of the matter referred to in the question, no report has been made upon administrative procedures necessary to give effect to the conclusions of the Commission. The Government have therefore assented to the proposal that a Royal Commission should be appointed to consider and report upon these matters. Legislation would be necessary to enable me to order the compulsory inspection of all cows whose milk is sold for public consumption, and I think it should be postponed pending the inquiry which has been determined on. In the meantime I may remind the hon. member that it is to be gathered from the report that by a very simple process—viz., by boiling the milk—immunity can be insured to the consumer.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BEATTY, J., M.B., B.S.Dubl., has been appointed House Surgeon to Dr. Steevens' Hospital, Dublin.

CALEY, JAS. W., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Riccall Sanitary District of the Selby Union.

CARSON, H. W., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Evangelical Protestant Deaconesses' Institution and Training Hospital, the Green, Tottenham.

DANIELL, G. H. S., M.B., B.C.Camb., has been appointed Medical Officer for the First Sanitary District of the Blandford Union.

Births, Marriages, and Deaths.

BIRTHS.

BEALE.—On April 19th, at Clapham-road, S.W., the wife of Arthur A. Beale, M.B. Glasg., of a daughter.

CLEASBY-TAYLOR.—On April 4th, at Alcaravaneras, Las Palmas, Grand Canary, the wife of — Cleasby-Taylor, M.D. Edin., of a son.

DONALDSON.—On April 15th, at Brent-road, Woolwich, the wife of Surgeon-Captain J. Donaldson, Army Medical Staff, of a son.

LOWNDS.—On April 15th, at Hall-gate, Doncaster, the wife of Henry Al Lownds, L.R.C.P. Edin., of a son.

PURCHAS.—On April 15th, at The Bank, Newtown, North Wales, the wife of F. Utten Purchas, M.D. Edin., of a daughter.

WHITAKER.—On April 21st, at Willoughby-road, Hornsey, N., the wife of George Herbert Whitaker, M.R.C.S., of a daughter.

WILLANS.—On April 14th, at Much Hadham, Herts, the wife of W. Blundell Willans, L.R.C.P. Edin., M.R.C.S., of a son.

MARRIAGES.

BRISTOWE—KARSLAKE.—On April 15th, at St. Peter's, Cranley-gardens, Hubert Carpenter Bristowe, M.D., of Wrington, Somerset, to Mary, daughter of Lewis Karslake, of Harcourt-terrace, Kensington.

BRYANT—LEWIS.—At St. Joseph's, Seacombe, April 14th, by the Rev. Canon Singleton, William Arthur Bryant, M.B., of Hull, to Catherine Smith (Tittiens) Lewis, of Seacombe, Cheshire.

GREENYER—LINDSAY.—On April 15th, at Holy Trinity Church, Upper Tooting, Vivian Tudor Greenyer, M.R.C.S. Eng., L.R.C.P. Lond., eldest son of George Greenyer, of Hove, Brighton, to Mary J. Douglas Lindsay, younger daughter of George Lindsay, of Balham, Surrey.

GROVES—ANDERSON.—On April 21st, at the church of St. Nicholas Cole Abbey, Ernest W. Hey Groves, M.R.C.S., L.R.C.P., to Frederica Margaret Louise Anderson, second daughter of the Rev. H. Anderson.

GUTHRIE—GODDARD.—On April 16th, at Illogan Parish Church, Cornwall, Roger Christian Lingard Guthrie, M.B., C.M. Edin., of Carnoustie, Forfarshire, to Ethel Annie Kennedy, second daughter of Henry Robertson Goddard, of Fairfield, Illogan, Cornwall.

KENDALL—CROSSE.—On April 15th, at Terrington, George William Kendall, B.A., M.B. Dubl., of Queensberry, Yorks, to Phillis, youngest daughter of the Rev. Marlborough Crosse, Vicar of Terrington St. Clement's, Norfolk.

STOKES—EASBY.—On April 8th at St. Mark's, Peterborough, by the Rev. B. de M. Egerton, M.A., assisted by the Revs. R. S. Pocock and H. Whittaker, W. Calcott Stokes, Esq., of Edge Hill House, Banbury, to Mary Elizabeth, eldest daughter of William Easby, M.D., of Westgate, Peterborough.

TATE—DALZELL.—On April 21st, at St. Benets and All Saints', by the Rev. A. C. Roberts, assisted by the Rev. H. Clark, brothers-in-law of the bride, Walter William Hunt Tate, M.D., son of the late George Tate, to Flora, widow of the late Dr. Anthony Dalzell.

TURNEY—FERGUSON.—On April 22nd, at St. James Episcopal Church, Inverleith Row, Edinburgh, by the Rev. William Jenkins, Horace George Turney, M.B., M.R.C.P., of 28, Wimpole-street, London, to Margaret, daughter of the late William Ferguson, Writer to the Signet, Edinburgh.

VENABLES-WILLIAMS—PARRY.—On April 15th, at St. John's Church, Chester, by the Rev. W. Venables-Williams, M.A., Oxon., Vicar of Llandrillo, Colwyn Bay, father of the bridegroom, assisted by the Rev. L. Garnett, M.A. Oxon., Rector of Christleton, and Rev. F. A. Screeton (Durham), Curate of St. John's, William Montagu Venables-Williams, J.P., county of Denbigh, L.R.C.P. and L.R.C.S. Edin., Colwyn Bay, to Sara A. A. Parry, second daughter of Albert Parry, Vicar's Cross, Chester.

WILLIAMS—LEIGH.—On April 14th, at St. Paul's Church, Portwood, Stockport, John R. Williams, M.B. Edin., of Penmaenmawr, to Annie Mary, elder daughter of the late James Leigh, of Manor House, Brinnington, Stockport.

DEATHS.

CRAIG.—On April 15th, at Waverley House, Worthing, John Craig, F.R.C.S., late of the East India Company's service.

GASON.—On April 12th, at Rome, John Gason, F.R.C.P., L.R.C.S. Irel., aged 79 years.

HENDERSON.—On April 19th (suddenly), at his residence, Stanhope-terrace, Regent's Park, Wm. Henderson, M.D. Glasg., aged 51.

HOLTTUM.—On April 21st, at Latchmere House, Watling-street, Canterbury, Charles Holttum, F.R.C.S., in his 79th year.

METCALFE.—On April 18th, at Massongex, Valais, Switzerland, John-William Metcalfe, M.D. Erlang, M.R.C.S. Eng., in his 78th year.

PARROTT.—On December 27th, 1895, at Lao-ho-k'ou, viâ Hankow, China, Annie W. Parrott, wife of Albert George Parrott, M.R.C.S., L.R.C.P. Lond., aged 40.

TOWNSEND.—On Sunday morning, April 19th, 1896, at 68, Queen's-gate, London, Mary Alice, wife of Thomas Sutton Townsend, of Clifton Manor, Warwickshire, and only daughter of the late Thomas Ainsworth, of The Flash, Cumberland, aged 45.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second half-yearly volume for 1895 was given in the issue of Dec. 28th. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*.; by post, 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

THE ENDORSEMENT OF A QUACK.

To the Editors of THE LANCET.

SIRS,—A. called me in to see his wife, who was suffering from secondary nodules in the skin around a scar left by the removal of the left breast and marked dyspnœa due to collapse of the left lung, probably due to a growth near its root. As I could not promise to cure the patient and gave a bad prognosis A. suggested I should watch her whilst a quack remedy was tried. I refused to be a party to this, as I considered I should be practically covering the quack and not doing the best for my patient, and threw up the case. Will you give me your opinion what is the proper course to pursue under like circumstances?

I am, Sirs, yours faithfully,

April 18th, 1896. F.R.C.S.

*** Our correspondent took the only possible course open to him. He could not, in however distant a manner, be a party to the employment of a quack remedy for the cure of malignant disease.—ED. L.

A CASE OF SOMNAMBULISM.

ON awaking one morning recently a Dutch farmer of Heerenneen (Drenthe) perceived with astonishment that his wife was no longer in bed beside him. In one corner of the room lay her shoes and in another her clothing, but of the good dame herself not a trace could he find anywhere about the premises. Greatly alarmed he called in the aid of the police, and all day long there was a most energetic search for the missing housewife, but without avail. At length, towards evening, a peasant came forward and said that shortly after daybreak he had seen a woman in her night clothes wandering about near the village of Bonenknype. At the time he was inclined to think it was an apparition, for in the uncertain light the figure had a most unearthly look, but perhaps, after all, he was mistaken. Upon hearing this tale the farmer at once started off in the direction indicated, and finally succeeded in finding his wife at the house of her sister, which is distant three leagues from Heerenneen. The wanderer had arrived there at about seven o'clock in a dazed condition and half dead with cold. She had no recollection of leaving her home and could give no account whatever of the journey she had undertaken in such extremely light marching order. Before reaching her sister's place she had to cross a score or more of narrow bridges, some of them mere planks, and was likewise obliged to jump several formidable ditches. The fact that under these circumstances she escaped an accident is looked upon by the simple peasantry as well-nigh miraculous, but seems to bear out the general supposition that people in a state of somnambulism are able to perform gymnastic feats which they could not attempt in their waking moments.

A NOVEL METHOD OF INTRODUCING A NEWLY-QUALIFIED MAN.

To the Editors of THE LANCET.

SIRS,—As one who holds the honour of the medical profession dear, who considers it should be looked on as a "learned profession" and not as an advertising business, and that there are other considerations which are of greater importance to him who has the privilege of being a member of the same than that of making money,—as one holding these views may I beg your opinion on the following, which was publicly "cried" on the evening of April 18th, 1896, in the village of ——, ——shire: "Dr. J—— has passed his degrees of the highest order in the shortest time." There was later an intimation given that he was coming to reside there on Thursday next. Surely Dr. J—— cannot be aware of this liberty taken with his name, and should take the earliest opportunity of repudiating any responsibility for such an advertisement of one barely on the threshold of the profession.

I am, Sirs, yours truly,

April 20th, 1896. VINDICATOR.

*** Our correspondent adds that Dr. J——'s advent had been previously advertised for three months on boards. There can be no doubt that the methods adopted by Dr. J——'s friends to introduce him to the notice of his future *clientèle* are utterly opposed to all the traditions of our profession.—ED. L.

SEATS FOR THE USE OF EMPLOYÉS.

THE *Boston Medical and Surgical Journal* states that the New Hampshire Legislature has passed a law compelling all employers of females in any manufacturing, mechanical, or mercantile establishment in the State to provide suitable seats for the use of females so employed. A fine of not less than $10 (£2) or more than $30 (£6) for each offence is the penalty prescribed for a violation of the law.

"A CARDIAC CURIOSITY."

To the Editors of THE LANCET.

SIRS,—A case somewhat similar to the one described by Dr. Fuller and Mr. Gibbs under the above heading in THE LANCET of April 4th recently came under my notice. The patient was a police constable, aged thirty years, enjoying good general health and on active duty. He had a loud mitral murmur distinctly audible through his clothes at a distance of several feet. He informed me that he had had two attacks of rheumatic fever, the last three years ago, and ever since then the murmur had been present. He showed no other symptoms except slight palpitation and occasionally slight œdema of the feet and ankles. In the course of his duty he had to walk from eight to twelve miles per day in a very hilly district.

I am, Sirs, yours faithfully,

JOHN CRAIG, L.R.C.P. & S. Edin., L.F.P. & S.G.

Wolsingham, Darlington, April 9th, 1896.

A TRANSLATION AT FAULT.

AN amusing blunder appeared in a French journal published, curiously enough, on April 1st. An account being given, translated from the *Vrach*, of the cure of two cases of diphtheria by the injection of *petit lait anti-diphtérique*. Anti-diphtheritic whey! It happens, however, that the Russian word "suivorotka" means serum as well as whey.

Doubtful.—The questions are very proper ones in the light of a possible marriage and should be referred to the medical attendant of the family. They do not all admit of a definite answer.

FILARIA SANGUINIS HOMINIS IN PHILADELPHIA.

ACCORDING to the *Philadelphia Polyclinic* living filariæ in the blood were for the first time demonstrated in Philadelphia last February, when Dr. F. P. Henry exhibited a number of microscope slides showing the embryos alive and active. The blood was drawn from the finger of a white woman, who was a patient in the Women's Hospital, and had developed hæmato-chyluria after labour. She was a native of South Carolina and had been in Philadelphia not quite one year. It was probable that the parasite had been acquired in the South and that rupture of a lymph vessel during the strain of labour had led to the chyluria; it was an example of the nocturnal variety, and was consequently not to be found in the blood drawn from the surface vessels during the day.

GOOD *v.* BAD VACCINATION.

To the Editors of THE LANCET.

SIRS,—I in large measure fully sympathise with "A London Doctor" who in a recent letter to the *Pall Mall Gazette* has deplored the sort of vaccination which, equally with the best, is declared to be "successful." He advocates the certification of the vaccination of an individual only after the operator has made four insertions, together with rigid examination of the person vaccinated by an expert giving up his time to this duty. Without going so far as this I would gladly see the instructions of the Local Government Board which bind public vaccinators made equally binding on all practitioners, and enforced if need be by Government examination, as is now done in the case of public vaccinators. The Government, while inspecting the results of vaccinations performed by officials over whom it has some control, is allowing other men a free hand. As a consequence certain members of the medical profession may, if they choose to look askance at vaccination as a prophylactic, comply with the letter of the law and infringe its spirit at will. I would, indeed, go a step further. We consider that it is desirable that a medical officer of health should be debarred from coming into competition in the way of ordinary practice with his professional brethren—at least that view is growing in the profession. Similarly I would see all vaccination relegated to properly appointed public vaccinators. The matter is of national importance. Then let it be done under central supervision and only by those who come under that supervision.—I am, Sirs, yours faithfully,

April 22nd, 1896. ONE WHO KNOWS.

Reproduction has not put his questions in very definite shape. The structure and physiology of the parts will be found fully given and freely illustrated in all standard works on anatomy. For the best authorities on the different pathological points we refer our correspondent to "Neale's Digest" (1840–1890), p. 498, *et seq.*

"A SKIN AFFECTION PRODUCED BY WORKING IN TEAK."

To the Editors of THE LANCET.

SIRS,—A gentleman was in my consulting room this forenoon who has had thirty years' experience of working in teak. I read the question on teak appearing in THE LANCET of April 21st to him and asked him if he could answer it. He said that he had never heard of any skin affection on the face or hands troubling carpenters when working with teak, but if the smallest splint pierces the skin, or if the skin gets abraded in the slightest degree when a carpenter is working with teak, the place is sure to inflame and suppurate. I am, Sirs, yours truly,

April 20th, 1896. M.B.

Inquirer is advised not to accept the lower scale, or at any rate only to do so after statement of his intentions to the present medical officer. We appreciate the fact that the difference in distance might account for a difference in remuneration, but to take a lower sum would have the appearance of underselling a fellow practitioner, and it is very important that just now even the appearance of such a proceeding should, in the best interests of the profession, be avoided.

AN UNFORTUNATE ERROR.

WE have received the following from the Rebman Publishing Company, Limited:—

"The Rebman Publishing Company beg to state with extreme regret that they have by mistake published a testimonial purporting to be from Dr. H. Davy of Exeter with reference to their calf lymph. The testimonial was given by Dr. H. Davy of Kimmage Lodge, Terenure, county Dublin. They have never received any testimonial from Dr. Davy of Exeter nor has he in any way communicated with them on the subject.

"Dated, April, 1896."

The company have done very right to make the *amende honorable* thus definitely to Dr. Davy of Exeter, whose annoyance at finding attributed to himself a testimonial that he did not give can be imagined. The incorrect address was given in pure error as we have had an opportunity of ascertaining.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

TUESDAY (28th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Mr. R. Barwell: On Spontaneous Dislocation of the Hip, with some Remarks on a Class of Case often mistaken for Rheumatism.—Mr. Mayo Robson: A Method of obtaining a Complete Skin Covering after Ablation of the Breast.—Mr. H. T. Butlin and Mr. Beadon Adams: On the Transplantation of Skin Flaps for the filling up of considerable Defects after Amputation of the Breast.

WEDNESDAY (29th).—SOCIETY OF ARTS.—8 P.M. Mr. E. W. Badger: Fruit Drying or Evaporation.

FRIDAY (1st).—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—7.45 P.M. Messrs. Maw, Son and Thompson will exhibit Surgical Instruments.—Messrs. Johnson and Johnson will show Surgical Dressings, &c. 8.15 P.M. The President (Mr. E. Clarke): Recent Progress in the Treatment of Diseases of the Eye.—Mr. T. Moore: Demonstration of the Roentgen Rays.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (28th).—ROYAL INSTITUTION.—3 P.M. Professor James Sully: Child-Study and Education.

THURSDAY (30th).—ROYAL INSTITUTION.—3 P.M. Professor Dewar: Recent Chemical Progress.

FRIDAY (1st).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. Dundas Grant: The Diagnosis and Treatment of various forms of Nerve-deafness.

ROYAL INSTITUTION.—5 P.M. Annual Meeting. 9 P.M. Col. H. Watkin: Chronographs and their Application to Gun Ballistics.

SATURDAY (2nd).—ROYAL INSTITUTION.—3 P.M. Professor W. B. Richmond: The Vault of the Sixtine Chapel.

During the week marked copies of the following newspapers have been received:—*Sheffield Telegraph, Manchester Guardian, East Anglian Daily Times, Folkestone Express, Leicester Post, Dundee Courier, Bedford Standard, Carlisle Journal, Northern Whig, Blackpool Gazette, Scottish Border Record, Worcestershire Chronicle, Bucks Herald, Bingley Chronicle, Times of India, Hastings Times, Pioneer Mail, Oldham Standard, Liverpool Courier, Architect, Liverpool Daily Post, Sussex Daily News, Keene's Bath Journal, City Press, Bristol Mercury, Western Daily Mercury, Sandbach Advertiser, South Wales Daily News, Western Mail, Hampshire Independent, Wakefield Herald, Bristol Times, Leighton Independent, Yorkshire Post, Builder, Westmeath Examiner, Ramsay Courier, Bradford Mercury, Newcastle Journal, Kentish Express, Leeds Mercury, Birmingham Gazette, Rochdale Observer, Scotsman, Citizen, Sanitary Record, West Middlesex Standard, Mining Journal, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Reading Mercury, Hertfordshire Mercury, Nottingham Daily Guardian, Bournemouth Visitor's Directory, Indian Mirror, Health, Practitioner, Surrey Advertiser, Local Government Journal, Gloucestershire Chronicle, Beverley Echo, Spalding Free Press, Galloway Gazette, Jersey Times, Le Temps (Paris), Edinburgh Evening News, &c., &c.*

A Presidential Address
ON
MEDICAL DIAGNOSIS.

Delivered before the North London Medical and Chirurgical Society on April 9th, 1896,

BY CHARLES KING, M.R.C.S. ENG,
LATE HONORARY SURGEON TO THE HOLLOWAY AND NORTH ISLINGTON DISPENSARY.

GENTLEMEN,—I had some little difficulty at first in deciding what should be the subject of this, my presidential address, but finally came to the conclusion that the question of diagnosis was one of general interest to us all, for in the practice of the profession of medicine and surgery the question which daily arises is, "What is the matter?" and the diagnosis of disease may fairly claim at our hands the paramount attention. For how can we treat our patients correctly or with any scientific pretension—how can we honestly give a prognosis unless we know what organ is at fault, the nature of the morbid process at work, and the extent of its ravages?

"Neque enim credunt posse eum scire
Quomodo morbos curare conveniat, qui unde hi sint ignoret."

Yet how often do we find difficulties arising, how often have we to confess ourselves beaten by the obscurity and complexity of the symptoms and physical signs? The making of a diagnosis does not begin and end with the labeling of a pathological condition or prominent symptom with a long name; the term must be understood and employed in a very much wider sense—it must include a conception as to how the organ has been affected from the first, the exact nature of the disease, and the resulting injury to the body generally as well as locally. To examine a patient who consults us for heart disease and then to say he has morbus cordis is not sufficient. It is not making a diagnosis—we must proceed further and make up our minds as to the nature of the change. Is the cardiac muscle primarily at fault? If so, what is the nature of the disease—is it fatty or fibroid degeneration or myocarditis? Is it a case of valvular disease? If so, what valve is affected and how is it affected? Is it incompetent or stenosed? Or are both conditions present? Another patient consults us for vomiting blood; to say he is suffering from hæmatemesis, again, is not enough, and we must endeavour to find out what the condition is due to. Is it gastric ulcer, carcinoma of the stomach, or cirrhosis of the liver?

During the last fifty years, since I was a student at Guy's Hospital, the advances in the science and art of diagnosis have, indeed, been great and wonderful; and to prove this we only have to look at the large number and the size of the text-books now entirely devoted to this subject. I might mention such works as Vierordt's "Medical Diagnosis," Finlayson's "Clinical Manual," Von Jacksh's "Clinical Diagnosis," and others. Methods of investigation have become more systematic and thorough. Our knowledge of anatomy, physiology, pathology, and chemistry is much more extensive. Many wonderful and ingenious instruments have been invented for investigating hitherto hidden parts, such as the eye, the larynx, and the bladder, for examining the blood, urine, and other fluids. I do not pretend to be practically acquainted with them all, but since I decided on the subject of my address to you this evening I have done my best to investigate some of the results which may be gained by their use, and for this purpose I have spent much time at my old school, where every facility has been afforded me for gaining this information.

A contrast.—How different are the surroundings of the student of to-day to what they were in 1846, when I was a clinical clerk under Dr. Addison. In those days a tablespoon and a candle were the only apparatus available in a medical ward for the detection of albumin in the urine. Now I see in all cases of albuminuria that an accurate record is kept of the amount of urine passed each twenty-four hours, of its specific gravity, reaction, amount of albumin and urea in addition to a description of the microscopical appearance of the deposit, and for this purpose every possible form of instrument and kind of reagent is at hand.

Successful diagnosis is an all-important adjunct to successful practice. In order to make an accurate diagnosis we must recognise abnormal physical signs, and not only recognise them, but interpret their special significance. This knowledge can only be obtained by constant practice, and we cannot obtain it by reading the experiences of others only, although by this means we get to know what to look for and to expect. We require a good general knowledge of anatomy and physiology, for if we do not know the normal structures and functions of the various organs, how can we expect to recognise their numerous diseased conditions?

Importance of morbid anatomy.—A knowledge of morbid anatomy is also of the greatest importance, and that is a science in which we who are general practitioners have little facility for becoming proficient. A good morbid anatomist as a rule is a good clinical physician. We should all become much more proficient in diagnosis, and our patient would in the end reap the benefit, if there were not that popular sentiment against the performance of necropsies in private. How much wider would our experience be if in doubtful cases we had opportunities afforded us of verifying or correcting our diagnosis by a post-mortem examination. How often do we sign a death certificate without any degree of certainty as to the exact nature of the immediate cause of death. I was shown two cases in the wards of the hospital which were supposed to be respectively types of the atrophic and hypertrophic forms of cirrhosis of the liver. One was a woman of alcoholic appearance aged about forty, with marked ascites and no jaundice and with physical signs of decrease in the size of the liver. She was pointed out as a typical case of atrophic cirrhosis. She died, and at the necropsy the case was found to be one of tuberculous peritonitis. The other case was that of a woman, also of alcoholic appearance, aged about forty-five, suffering from jaundice, sickness pain, and evidence of a very large liver. She was pointed out as a typical case of hypertrophic cirrhosis. She died, and at the necropsy the case was found to be one of carcinoma of the liver. In private practice both would have been certified as cases of cirrhosis of the liver and would have been classed under that heading in the at present useless statistics brought out by the Registrar-General. Morbid anatomy in these cases not only exposed our ignorance but added to our knowledge and rendered the probability of a correct diagnosis being made in similar cases in the future more likely.

The fallacy of lightning diagnosis.—In order to recognise the signs of disease we have especially to employ our senses of vision, touch, and hearing. In many instances we may be tempted to employ our eyes only, making a diagnosis it may be to impress our patients with a sense of our smartness, but it will not pay in the end. We should not get into the habit of making lightning diagnoses. We may succeed brilliantly for a time, but sooner or later a miserable failure will be the inevitable result. However, there are some cases in which we can detect the nature of the disease simply from the general appearance of the patient. The large white man has probably large white kidneys; the prominent eyes—staring, terrified expression—and the enlarged thyroid gland are characteristic of exophthalmic goitre; the broad, expressionless face, with bright-red patches on either cheek, the spade-like hands, the scanty hair, the thick, blurred articulation and monotonous voice, of the patient suffering from myxœdema; the livid cheeks, nose, ears, and the clubbed and livid fingers and toes speak of congenital heart disease; the tremor and general condition of flexion of paralysis agitans; the withered, shrunken, old-mannish appearance of the child of congenital syphilis; and there are other examples too numerous to mention.

Importance of noting slight symptoms.—The severity of the symptoms of any particular disease may vary considerably in different individuals. A strong man may become very ill without his knowing there is very much amiss, whereas a delicate, susceptible woman may feel the slightest ache or pain and attach the greatest importance to any departure from normal health. We should therefore observe the idiosyncracies of our patients, and certainly never let any of them imagine that we treat the description of their symptoms with scorn. Some patients are unskilful in describing symptoms, others are too graphic and elaborate. We must learn to discriminate, and take an accurate estimate of the

Digitized by Google

evidence before us. We must also remember that if a patient comes to consult us—no matter how slight the cause may seem—there must be some good reason for his doing so, and we should be just as careful with trivial as with grave cases.

Local causes of diseases should be carefully sought for, and we should not be too ready to treat a prominent symptom without finding some adequate cause for it. Every third-rate druggist has a bottle of medicine for every symptom for which he may be consulted. I know of a case which speaks strongly on this point. A woman aged about fifty-five consulted a druggist for diarrhœa and for four months was made the receptacle of the various astringent drugs of the pharmacopœa. She gradually became worse, and her medical attendant then found her trouble was due to carcinoma of the lower part of the rectum! I could give other illustrations on this point, but shall be content by mentioning the curious fact that asthma may be caused by disorders of the uterus and its appendages, and the importance of examining the pelvic organs in this disease when no other adequate cause can be found. In one of the New Sydenham Society's books[1] there is an interesting lecture on this subject by Dr. Alexander Peyer. Many diseases begin acutely with rigor and rise of temperature, and it is thus of importance to determine the manner of the onset. Some of the acute specific fevers—variola, scarlet fever, pneumonia, pleurisy, acute tonsillitis, and influenza—commence, as a rule, in this way. But variola for the first three days until the appearance of the characteristic eruption may be mistaken for scarlet fever. Influenza may be mistaken for scarlet fever. In such instances our clinical experience is found of the greatest value in making a differential diagnosis.

The significance of abdominal pain and of headache.—In many diseases one symptom may stand out prominently and attract all our attention as well as that of the patient. I allude to pain. Abdominal pain is a very common symptom of disease and the causes are legion. It may be due to gastric disturbance or it may be associated with sclerosis of the posterior columns of the spinal cord. Is its nature paroxysmal and colicky? Is it associated with jaundice and tenderness in the right hypochondrium? Then it is probably due to gall-stones. Is it associated with hæmaturia and does the pain run down in the direction of the ureters and cause retraction of the testicle? Then there may be renal calculus. Is it associated with constipation? Then it is important to examine the gums: it may be due to lead-poisoning. Peritonitis is another cause; and if the pain has come on suddenly with collapse it may arise from perforation of one of the abdominal viscera. Deep-seated pain may be due to malignant growths or to aneurysm. Pain is often associated with pulsation of the abdominal aorta. But on this account abdominal aneurysm should not be diagnosed every time we feel the abdominal aorta pulsating. Severe abdominal pain and vomiting may occur in locomotor ataxy, and very often is one early sign of this disease before ataxy is marked. The actual cause is very often overlooked, and such cases have been treated for gastritis, gastric ulcer, or gastric carcinoma. Therefore, in all cases of long continued and severe abdominal pain and vomiting we must examine the pupils and the knee-jerks. If the Argyll-Robertson pupil is found and the knee-jerks are absent locomotor ataxy will be the cause of the abdominal symptoms. Again, abdominal pain may be the most marked symptom of pneumonia or pleurisy, or, on the other hand, may be a prominent symptom of spinal caries. The moral to be drawn is that in cases in which abdominal pain is a prominent symptom a very careful and systematic examination must be undertaken to discover the cause.

Headache is another every-day complaint, and its causes are innumerable and require a very careful and systematic examination before treatment can be adopted. It may be due to disordered functions of the alimentary canal or generative organs; to errors of refraction; to toxic substances circulating in the blood; to alcoholism; to uræmia; to pathological changes in the brain and meninges; to cerebral tumours and meningitis; to diseases of the scalp and the cranium; and to many other causes.

The nervous system.—I have stated that a knowledge of anatomy and physiology is an important basis for diagnosis, and this in particular applies to the nervous system, for a familiarity with its normal structures and functions is indispensable for a recognition of its derangements. We must bear in mind how complex is that structure, with its nerve cells, ganglia centres, and nerve fibres, which conduct afferent and efferent impulses governing the movement and especially the nutrition of all parts of the body. The whole of the nervous system may be mapped out into areas, each of which has a certain connexion with special functions or particular parts of the body. The researches of Ferrier, Schäfer, Horsley, and others have so greatly increased our knowledge of localisation and special function within the last few years that we now know important facts not dreamed of in my student days, as that the convolution on either side of the fissure of Rolando controls the movements on the opposite side of the body; that in the posterior part of the third left frontal convolution the centre for articulate speech lies, and that a lesion here causes motor aphasia; that the visual centres are located in the occipital lobes, and the auditory centres in the first temporo-sphenoidal convolution. This knowledge of cerebral localisation has led to most important results, for now we can diagnose the exact seat of many lesions of the nervous system which are capable of cure by appropriate means. Again, our knowledge of the course of the pyramidal fibres from the cerebral cortex to the muscles and the effects of lesions in the various parts is an important aid to diagnosis. This point can be well illustrated by facial paralysis. If the lower part of the face only is affected and if twitching movements are noticed to occur at frequent intervals on the affected side it will be most probably due to a lesion affecting the facial cortical motor area on the opposite side of the brain. If it is associated with paralysis of the arm and leg on the same side of the body the lesion will be in the opposite internal capsule; if the arm and leg on the opposite side of the body are paralysed the lesion will be in the pons; and if the whole of one side of the face is paralysed and wasting of the muscles has occurred it points to a lesion of the nerve or its nucleus.

The kidneys.—Our knowledge of the diagnosis of disease of the kidneys has been much improved during the last twenty or thirty years on account of the increased care with which the urine is examined, for not only do we submit this important excretion to elaborate chemical analysis, but also take into consideration the variations which take place in its general characters. Deposits are submitted to careful microscopical examination, and by this means most important data for an accurate diagnosis can be obtained. In obscure abdominal tumours a change in the urinary excretion will indicate in many cases that the kidney is the seat of the disease. For example, if there is a large deposit of pus and the urine is acid we think the abdominal tumour may perhaps be a tuberculous kidney or a pyonephrosis; if a further examination of the pus is made and tubercle bacilli are found then we know it is a tuberculous kidney. Again, the variation in the amount passed is of importance. In one case a patient was suffering from a large abdominal tumour which was supposed to be a malignant tumour connected with the liver. A careful record of the daily amount of urine passed was kept and found to be an average of fifty ounces. One day, however, he passed 120 ounces, and when the abdomen was examined the tumour could not be felt. Some weeks afterwards he complained of difficult micturition and pain at the end of the penis. On sounding his bladder a vesical calculus was found. The abdominal tumour had evidently been a hydronephrosis which had been caused by the calculous obstruction.

Diseases of female pelvic organs.—Great advances have also been made in the diagnosis of diseases of the female pelvic organs. Dr. Cullingworth, in a clinical lecture[2] on this subject, says: "To-day I should be ashamed for any of my clinical clerks to be found at the close of their three months' tenure of office unable to diagnose, under reasonably favourable conditions, the size, position, consistence, and mobility of the Fallopian tubes, even if not of the ovaries as well, with a fair amount of accuracy"—a statement which would have been scoffed at a few years ago. These improvements have been brought about by as often as possible confirming the original diagnosis by subsequent examination on the operating table and in the post-mortem room as opportunities offered themselves. The introduction of the dorsal position, in addition to the left lateral position, by means of which a

bimanual examination can be more thoroughly conducted, has also been an important factor in bringing about these improvements.

Skin diseases.—In the diagnosis of skin diseases difficulties often arise as symptoms are so liable to differ and they are so rarely pathognomonic. It is of special importance to note the nature and distribution of the lesion or lesions present. Some diseases are very rare but their form so characteristic that the diagnosis is not difficult, as in the case of favus. We must also not forget that an eruption may be factitious—eczema, impetigo, pigmentation may all be artificially produced by malingerers and hysterical young women. It is not, as a rule, difficult to detect the fraud when once our suspicions are aroused. Again, in all cases of dermatitis the irritant should be sought for: pediculi in the hair are often the cause of impetigo, eczema may be caused by objects handled in the patient's trade, and pruritus vulvæ in women by diabetic urine. Cutaneous eruptions may be caused by the acute specific fevers, when the use of the thermometer will be of assistance, yet variola or varicella may be mistaken for acne or impetigo. The diagnosis of possible syphilis as the cause of the skin lesions is by no means a simple matter in many cases and requires all the care and judgment of which the practitioner is capable. Many skin diseases have characteristic distributions: psoriasis on the extensor surfaces of the knees and elbows; lichen ruber planus on the flexor surface of the elbows; acne vulgaris on the face, forehead, and back; and lupus erythematosus on the nose and cheeks. In all cases of skin disease it is of the greatest importance to examine every part of the body affected with the lesion. Many incorrect diagnoses are made through not following out this rule. Psoriasis may affect the scalp and may simulate seborrhœa and be diagnosed as such, whereas a systematic examination would have revealed the characteristic lesion of the disease on the extensor surfaces of the knees and elbows. Some diseases affect the deeper layers of the skin and are characterised by scarring, and the diagnosis between tuberculous dermatitis and syphilis is often extremely difficult on this account. The parasitic diseases may be detected by microscopical examination, which in the case of the vegetable parasites will reveal the characteristic spores and mycelium.

The clinical thermometer.—The clinical thermometer did not come into general use until after the years 1850 and 1851, when very great attention was called to its importance by the papers published on the subject by Traube and Bärensprung respectively. Wunderlich of Leipzig then devoted himself to the study of the temperature in every variety of disease, and his well known work, which has been translated and published by the New Sydenham Society, is still the standard work on this most important subject. In England the clinical thermometer was first adopted by Parkes, Ringer, and Aitkin. It is now, of course, in the hands of every medical man, and in determining the presence or absence of pyrexia and the course, duration, and degree of pyrexia its value as an aid to diagnosis cannot be over-estimated. We know that the temperature runs a definite course in certain diseases, so that if a careful record has been kept and recorded on a chart the nature of a doubtful case may often be thus cleared up. The sudden rise, the continuous character for five or six days, followed by a crisis, are all familiar to us as characteristic of lobar pneumonia; the gradual rise followed by the continuous type which ends about the end of the third week by lysis of typhoid fever. In this last-mentioned disease we should remember also the importance of taking the temperature for some time after the lysis, for the only indication of a relapse may be the rise of temperature. It is also of great importance to note the state of the pulse- and respiration-rate to the rise of temperature; in ordinary cases, the pulse, respiration, and temperature rise synchronously. In some diseases, however, there is a considerable variation from this; for instance, in typhoid fever with a temperature of 104° F. the pulse may be only 80, and an observation of this point is an important aid to the diagnosis of the case. Again in pneumonia and broncho-pneumonia with a temperature of 104° the respiration-rate may reach 60 or 70 to the minute, and such an observation at once points to the lungs as being the primary seat of the disease. In cases of wasting and weakness without definite evidence of organic disease pyrexia indicates, with a considerable degree of probability, tuberculosis. A single rigor accompanied by a rise of temperature to 104° or 105° may lead to the diagnosis of suppuration, especially if it occurs in a patient who is suffering from gall-stones or renal calculi.

The ophthalmoscope was invented by Helmholtz in the year 1851, and by its means he was able to study the details of the hitherto unseen lining of the fundus oculi, retina, and choroid, and thus was the pioneer of one of our most certain and helpful diagnostic instruments. We may have a patient suffering from œdema of the legs, ascites, enlarged liver, and hypertrophied and dilated heart and albuminuria, and the question which often arises is, Is this a case of primary heart or kidney disease with secondary cardiac trouble? The ophthalmoscopic examination may reveal the presence of albuminuric retinitis, and we forthwith make our diagnosis of primary renal disease. We have another case suffering from pyrexia and diarrhœa which does not present to us the typical picture of typhoid fever. An ophthalmoscopic examination may reveal the presence of tubercles in the choroid, and then a diagnosis of acute tuberculosis is made. In cases of severe and persistent headache also an examination of the fundus oculi is of the greatest importance, for the causes of headache are innumerable. If, however, optic neuritis is found we know we have a gross cerebral lesion to deal with and treat our patient accordingly.

The laryngoscope.—The laryngoscope was first introduced into medical practice by Türck and Czermak of Vienna in the year 1857. Now it is in the hands of every general practitioner, and its use in the differential diagnosis of diseases of the larynx is invaluable. By its means such hitherto invisible structures as the epiglottis, aryteno-epiglottidean folds, vocal cords, and trachea can be examined by the eyes; and syphilitic, tuberculous, and malignant ulceration can be differentiated. In the girl suffering from hysterical aphonia the vocal cords can be seen widely separated through paralysis of the adductors. The deep-seated intra-thoracic aneurysm which is pressing on the recurrent laryngeal nerve and which has given rise to few other characteristic signs may be diagnosed by the discovery of the abductor paralysis of the corresponding vocal cord by the systematic use of the laryngoscope in such cases. New growths may be diagnosed and removed by the aid of this instrument and important facts gained by its routine use.

Examination of the blood.—In the differential diagnosis of anæmia it is of great importance to investigate the conditions of the red and white blood corpuscles and hæmoglobin, and for this purpose several ingenious instruments have been introduced. Vierordt in 1854 was the first observer to determine the corpuscular richness of the blood, and he did so by allowing blood diluted to a known degree to dry on a glass slide and then counting the corpuscles by means of a microscope and micrometer. He ascertained that a healthy adult man should have about 5,000,000 red blood corpuscles to the cubic millimetre. Since then Gowers, Thoma, Zeiss, and Malassez have introduced more elaborate instruments by means of which the percentage number of corpuscles and the percentage amount of hæmoglobin can be determined. The importance of such examinations can be illustrated by the characteristic changes which are generally present in the following diseases. In chlorosis the red blood corpuscles are rarely reduced below 60 per cent. of the normal, whereas the hæmoglobin may be reduced to 20 per cent. of the normal, and the white are not increased. In pernicious anæmia the red blood corpuscles may be reduced to as low as 10 per cent. of the normal, but the hæmoglobin not to a corresponding degree, so that in this disease the individual value of each red blood corpuscle for hæmoglobin is greater than normal—a condition diagnostic of this disease. In addition the red blood corpuscles are changed in shape, and nucleated red blood corpuscles may be found. In leucocythæmia there may be a large excess of white blood corpuscles, and in extreme cases they may exceed the red in number. There is another most important condition in which the microscopical examination of the blood is of importance and that is in malaria, in which disease plasmodial bodies may be detected in the red blood corpuscles. The discovery of these bodies may help us considerably in diagnosing this disease from other fevers and also from the form of the plasmodia in determining the particular kind of malaria.

Examination of the bladder and urethra.—By means of an instrument called the electric cystoscope the interior of the bladder can now be illuminated. Dr. Nitze of Berlin conceived and carried out this idea in 1879. The illumination was derived from a platinum loop. This was, however, supplanted in 1887 by an incandescent lamp, which change-

Digitized by Google

has rendered the instrument much more simple and less costly. Its value in surgical diagnosis has been proved by many surgeons in England, and Meyer of New York in 1889 wrote: "There is no doubt in my opinion (and no surgeon doubts it any more to-day) that cystoscopy has a great future. Of course, we have yet to learn in many respects to recognise the disease in the picture, and may often be mistaken in explaining what we see—just as may occur to laryngologists, and very experienced ones, with diseases of the larynx." This instrument is of especial use in the diagnosis of symptomless hæmaturia. The orifices of the ureters can be examined, and if blood is of renal origin it may be seen issuing from the ureter or ureters. Papillomatous growths, encysted calculus, hæmorrhagic cystitis, and enlarged prostate can be detected—in fact, it is a most important aid to the diagnosis of obscure disease of the bladder. Dr. Nitze has also introduced another ingenious instrument, the photocystoscope, by means of which photographs can now be taken of the interior of the living bladder.

Bacteriology is a very important aid to diagnosis, since so many diseases are due to definite specific micro-organisms which are recognised by their special form and reaction to stains and manner of growth in culture media. Of course, this method of research cannot be carried out by the general practitioner, but at a small cost it can be done for us by the Clinical Research Association. The importance of this method applies in particular to the diagnosis of diphtheria and tuberculosis. So far as the diagnosis of diphtheria is concerned the modern physician does not feel comfortable or satisfied unless in at any rate all doubtful cases of sore-throat the opinion he gives is confirmed by bacteriological diagnosis. The diagnosis of phthisis has become much easier and can be made much earlier and with greater certainty since the discovery of the tubercle bacillus and its significant reaction to certain stains. In all suspicious cases of chronic lung disease an examination of the sputum should be made for these micro-organisms. Cholera is another disease in the diagnosis of sporadic cases of which a bacteriological examination for the comma bacillus is necessary.

Very great interest has been centred during the last few months in the so-called "new photography," the latest and one of the most startling and sensational scientific discoveries with which the name of Professor Roentgen is popularly associated. The chief medical interest in this discovery lies in the fact that bone is opaque and flesh transparent, so that by means of these rays the skeleton of a living body can be photographed, as shown in the beautiful photographs reproduced in our medical journals; and in this way the nature of deformities, obscure fractures, and dislocations can be accurately determined. It is almost impossible at present to realise the full importance of this discovery as an aid to medical and surgical diagnosis; but, judging from the great advances already made, it seems possible that not only injuries of bone and foreign bodies in the tissues may be seen, but the diagnosis of such obscure conditions as renal and biliary calculi will be much facilitated. Another tribute to the immense importance of this discovery is the fact that one of these photographs has been accepted in a court of law as evidence of injury and substantial damages awarded in consequence. I quote from the report which is taken from the *Sun* of March 8th, 1896. "The Roentgen Rays in Court.—The Roentgen rays penetrated yesterday into the Assize Court at Nottingham, where Mr. Justice Hawkins was sitting at *Nisi Prius*. Miss Gladys Ffolliott, an actress, claimed damages from the Nottingham Theatre Company for injuries sustained through a faulty staircase in the defendants' theatre. During the hearing of the case a London medical practitioner produced in evidence negatives of the plaintiff's left foot taken by Professor Ramsay by means of the new 'x' rays. The negatives showed that the bones of the foot had been displaced. Mr. Justice Hawkins remarked that nowadays a man might be sent to an asylum by having his head photographed. Verdict for the plaintiff, damages £76 10*s*."

Gentlemen, I now beg leave to conclude. In doing so may I be allowed to thank you for the honour you conferred on me by placing me in this chair, and may I also express my sincere and cordial thanks to the honorary secretaries of this society, Dr. James Galloway and Dr. E. S. Tait, for the kindness and the able support I have received from them during the whole of my term of office?

THE CAUSATION AND TREATMENT OF MAMMARY ABSCESS.[1]

BY A. MARMADUKE SHEILD, M.B, B.C. CAMB., F.R.C.S. ENG.,

ASSISTANT SURGEON AND LECTURER ON PRACTICAL SURGERY AT ST. GEORGE'S HOSPITAL.

IN these days of striking novelties in surgical matters there is always an inclination to commence with an apology when one writes a paper upon a medical or surgical malady of common occurrence, which is ordinarily met with in practice, and the diagnosis and treatment of which are supposed to be generally well known. Such a subject is suppuration within the mammary gland, and I have been induced to bring it forward because of its importance in all classes of practice, and because I feel sure that the operative treatment of mammary abscess as ordinarily conducted is by no means satisfactory in its results. The very commonness of the affection would serve as a sufficient plea for my bringing it before a society where men of all varieties of practice meet on common ground. There are many points regarding mammary suppuration of great interest. Not the least are some of the modern methods of treatment and the frequent diagnostic difficulties that from time to time arise. As regards the causation of these affections, though everyone connects them with suckling and lactation, yet instances occur in practice which are quite inexplicable on these grounds, and it is here that the special diagnostic difficulties arise which renders the subject of mammary abscess so immensely important to surgeons. Taking first the common form of acute mammary abscess I need only state a few figures to show its close relation to lactation. The total number of cases of abscess of the breast admitted into St. George's Hospital between 1870 and 1895 was 200. The right breast was more commonly affected. Both breasts were affected in 13 instances. There were 2 cases affecting males: 1 due to pyæmia and the other to a blow. Out of the 200 cases 169 were directly due to lactation and referred to sore nipples in women of the child-bearing age. 31 were due to other causes; of these, 8 seemed directly attributable to a blow, 1 was due to necrosis of a rib and 22 were due to no certain cause; but of these in 5 instances the abscesses originated on the site of former abscesses, and there was in three a suspicion of the affection being tuberculous. In the 22 cases the patients were either young girls or women between forty and sixty years of age. The youngest were eleven and fifteen and the oldest fifty-eight and sixty-seven years of age. In only 2 cases was the abscess submammary. In the majority of instances the pus was within the gland substance itself. In several of the older patients the abscess was thought to be a solid tumour, and the true nature was only discovered after exploration.

In like manner I have studied sixty cases of abscess of the mamma admitted into University College Hospital for six years, from 1884 to 1890, selecting that period because then alone were full particulars given of the nature of the abscesses and the time they occurred after lactation. Of the 60 cases, 51 were associated with pregnancy or lactation in women of varying ages. The left breast slightly preponderates in order of frequency of attack. Of cases of chronic abscess there were eight occurring between the ages of thirty-five and fifty-one years. In one of these blows were mentioned as a likely cause. Several of the chronic abscesses were only differentiated from scirrhus by exploratory incision, being associated with ulceration of the nipple, and in one the nature of the contents seemed likely to show that the supposed abscess was really an ancient galactocele with inspissated contents. One case of acute superficial abscess occurred in the male breast just beneath the areola, and no cause could be assigned for it. Of 102 cases of abscess related by Bryant[2] 79 occurred during lactation, two during pregnancy, and 21 in non-lactating, non-pregnant women. Birkett[3] in examining 149 cases of mammary suppuration noted that 132 of them occurred

n suckling women. Among 72 cases published by Nunn 38 occurred in lactating women, 7 in pregnant women, and 7 in non-puerperal women. Of 230 cases collected by Jamain and Terrier[4] 183 were connected with the puerperal state, 47 occurred during pregnancy, and 34 were not connected with either condition. McClintock[5] preserved notes of 82 cases of mammary abscess and found the preponderance on the left side. Of all the abscesses he had seen the vast majority made their appearance during the first six weeks of lactation. As regards the time after parturition that mammary abscess occurs I find the greatest variability. Some of the cases occur as early as the first, others not until the fourteenth month. Birkett[6] found that in 116 cases half of them occurred as early as the first month after parturition, and a large proportion of these as early as the first week. In 50 of the St. George's Hospital cases collected by myself, where the time after parturition is noted, the majority occurred later than this, 38 cases occurring in the period between the second and the fourth month. Bryant[7] found that out of 102 cases 68 occurred in the first two months after pregnancy. It would seem very difficult if not impossible to strike an average regarding the exact month at which lactation abscess is the more common; but Nunn, Birkett, and Bryant are all agreed that this affection is most frequent in the early and late months of pregnancy. Birkett[8] estimates that half of the cases are associated with defective or sore nipples. Personally, I believe the average is far higher than this, and I have never seen a case of acute mammary abscess in a young woman without being able to observe, by the aid of a lens, breaches of surface in the vicinity of the nipple by which organisms might readily enter the lymphatic channels. Through the courtesy of Dr. Griffiths and Dr. Grigg I have been able to inspect the records of Queen Charlotte's Lying-in Hospital, and I was greatly struck at the remarkable infrequency of mammary abscess at that institution. Out of 2000 cases examined by myself, taken by selecting 200 at a time, out of different years in the practice of various physicians, to my surprise not a single case of mammary abscess was found. The medical officer was obviously on the alert to note such conditions, for cases of "milk-engorgement" with threatening inflammation were here and there noted. It is true that the majority of parturient women were early discharged from the hospital, say, in a fortnight or three weeks; but, on the other hand, it must be pointed out that most of the patients were primiparæ in whom the nipples are often badly developed, badly cared for, and frequently sore. The cause was not far to seek in the precautions taken by the physicians to ensure the cleanliness of the nipples and of the infant's mouth, and this brings me to enunciate the first important proposition of this paper, that in the vast majority of cases acute mammary abscess, whether during lactation or not, and in either sex is due to absorption by the lymphatics of organisms, which enter abrasions on the nipple or areola. The common organisms found on the skin can nowhere be more abundant than in the axilla or about the areola of the mamma—parts moist and protected and affording every opportunity for active increase and growth. Moreover, round the nipple is a fossa kept moist by the secretion of especial sebaceous glands, and in such a locality organisms most abound. The least breach of surface is inoculated as surely as though the surgeon had rubbed in the virus intentionally.

During lactation the vascularity of the breast and the rapidity and vigour of its lymphatic circulation render absorption very marked. The organ is engorged with blood and full of an animal fluid, affording an excellent medium for the proliferation of organisms. All these considerations are sufficient to explain why the least breach of surface about the nipple of a lactating breast so readily leads to abscess. Modern investigations into the true causes of suppuration exclude engorgements of the mamma as having anything to do with mammary abscess except as a predisposing cause. In former days the milk was thought to be the cause of mammary and puerperal affections. Thus, puerperal insanity was termed 'mania lactea" and iliac phlebitis was commonly termed 'milk-leg." These erroneous terms were first publicly denounced by Meigs, who applied the contemptuous epithet of "milkmen" to his professional opponents. The organisms found on the skin capable of originating suppuration are probably numerous and need not here be enumerated. Modern writers on dermatology, especially in Germany, have recognised the fact that many of the suppurative affections of the skin associated with local infective qualities, as boils, pustules, and impetiginous eczema, are due to the entrance of organisms, especially staphylococci, by minute abrasions or by the mouths of the ducts of the sebaceous glands.[9] Dr. Slater, bacteriologist to St. George's Hospital, has kindly examined for me the pus taken from acute mammary abscess. In all of the cases abundant staphylococci were found, principally the staphylococcus aureus. Jamain and Terrier are of the same opinion.[10] "Abscess of the breast," write these authors, "is the result of infection." The most common agent is the staphylococcus, sometimes the streptococcus, and, according to Bumm, in exceptional instances the gonococcus. In accordance with the view that all cases of acute mammary abscess are due to the entrance of organisms from the neighbourhood of the nipple, I must view with doubt those cases of so-called acute idiopathic abscess that occur in the unimpregnated condition. Among the St. George's Hospital cases are found instances of acute abscess occurring in girls as early as the age of fifteen and eleven years, and no apparent cause was to be found. In neither of those cases was an examination made of the nipple and areola with a lens, and without such precaution an abrasion may be readily overlooked. I had an opportunity of observing an important case which bears out this view under the care of Mr. Pick in the wards of St. George's Hospital during the past year. A middle-aged, healthy-looking single woman had noticed for about a year that the left nipple was occasionally "a little sore." A week before admission she had complained of acute pain in the left breast with some swelling. There was an apparent tumour the size of an orange in the left breast, hard but markedly tender, with a sense of elasticity towards its centre and a faint red blush on the skin. At the base of the nipple was a small abrasion covered by a scab. The appearances were very similar to scirrhous cancer. An exploratory incision evacuated creamy pus, which was examined by Dr. Slater and found to contain the staphylococcus aureus in abundance. The abrasion on the nipple might readily have been overlooked without close examination.

Although in the numerous instances where chaps and excoriation about the nipple become infected with organisms, the staphylococcus — especially the staphylococcus aureus—appears to be common, yet there is nothing to prevent organisms of a more virulent nature from entering the tissues. This will perhaps explain cases which the older writers used to term diffuse phlegmon of the breast, where the tissues became gangrenous and the patient rapidly sank. Such cases are certainly rare. I have never seen one, and they are scarcely mentioned by modern surgeons. Velpeau[11] notices the case of a healthy and powerful young woman, who was neither pregnant nor recently confined, who was attacked with what was considered to be "erysipelas" near the left nipple. The swelling increased with a rapidity similar to that observed in the scrotum, eyelids, or cellular tissue elsewhere. A large gangrenous patch formed over the external half of the gland and the patient rapidly sank. In such a case modern investigation would probably have discovered such organisms as streptococci and the bacillus septicus.

The cases, says Spiegelberg, in which abscess of the mamma is part of general septic infection must be very few. Rokitansky mentions the occurrence, and other cases are related by McClintock and one by Spiegelberg[12] himself. McClintock's case of abscess due to general septic infection is referred to in his clinical memoir on diseases of women (page 325). "Only one example has fallen under my notice in which I felt satisfied the abscess of the breast was purely symptomatic. In this instance it succeeded to uterine phlebitis. An enormous swelling, attended with great pain and some discolouration of the skin, formed in the superior part of the right mamma extending upwards to near the clavicle. On dissection, an immense quantity of unhealthy purulent fluid was infiltrated throughout all

the structures of the part." The records of the Middlesex and University College Hospitals show us no examples of pyæmic abscess of the breast, and it is not mentioned by writers of repute. I have only been able to find one case of abscess of this nature in the records of St. George's Hospital in twenty-five years, though it is right to point out that in fatal cases of pyæmia a small abscess in the breast may readily have been overlooked. A feeble man was admitted into St. George's Hospital on July 30th, 1884. He was too ill to give an account of himself, but it was gathered from his wife that he had been ailing for about ten weeks with "aches and pains all over him." Five weeks before admission a painful swelling began to form in the left breast and right nipple. On admission a large abscess was opened in the left breast, and an incision over the right inner malleolus was made through brawny indurated tissue. This patient remained in the hospital for nearly seven months with all the symptoms of chronic pyæmia, abscesses being opened in the buttock, the calf of the leg, and the sterno-clavicular articulation. He finally recovered after a severe and protracted illness. The primary focus of infection was doubtful, but abscess undoubtedly first formed in the left mamma.

I have asserted that the vast majority of cases of acute mammary abscess are caused by the direct action of organisms which enter the lymphatic channels. There yet remains another possible method of infection which is of the highest interest and which possibly has not received the attention it deserves—i.e., the entrance of organisms along the milk ducts themselves. I have already referred to the fact now well known among dermatologists that organisms may enter the sebaceous glands of the skin and thus produce the phenomena of boils and pustules. Seing that the breast is only a highly differentiated sebaceous gland one suspects that the same might here occur. Nocard of Lyons produced tuberculous mammary abscess by injecting tuberculous virus into the milk ducts of a lactating goat. Boissard in a clinical lecture delivered in Paris in 1893[13] speaks very positively of the invasion of the milk ducts by streptococci and staphylococci. He terms the resulting suppurative affection galactophoritis. Chassaignac called the disease canalicular intra-mammary abscess Nyeth[14] relates the case of a woman aged forty-two years who was non-lactating and affected with bilateral mammary abscess which burrowed through and destroyed both breasts. He terms the case infection of the mammary gland through the nipple and galactophorous ducts. The destruction was so extensive that both breasts were ultimately amputated, which seems a very severe remedy. The branching nature of the abscesses along the milk ducts seems especially to impress the writers upon galactophoritis. It is always open to doubt in these cases that some breach of surface does not really exist, and although the experiments of Nocard place it beyond doubt that infection by the ducts is possible it is certainly not common. For three years I have closely examined a number of cases of mammary inflammation and abscess without finding a single case where I could certainly attribute the abscess to infection through the milk ducts themselves. Moreover, in 1894 Professor Sherrington and myself performed two experiments at the Brown Institute which had a negative result. In a lactating cat and a lactating rabbit milk was squeezed from the mammary gland, and where the ducts were empty and ready for absorption pus was well rubbed into their orifices and allowed to dry there. In one case fresh pyæmic pus was used, in the other secretion from a tuberculous abscess. In neither of the cases did any reaction or alteration occur. I think these two experiments, which were carefully done, go some way to show that suppurative processes do not readily pass along the milk ducts of animals. What the effect of gonorrhœal pus upon the milk ducts of the human subject may be it is, of course, impossible to prove by experiment; but judging by the way it affects the urethra one would imagine that purulent inflammation would readily result. The principal importance of purulent inflammation of the milk ducts are the serious results which may possibly occur to the infant. We hardly yet quite understand the extraordinary influences which the mother's milk may exercise on the infant for good or bad. We, indeed, are aware that certain drugs are excreted with the milk and that emotional disturbances and febrile attacks on the part of the mother have deranged the digestive system of the infant. The presence of pus in the milk would be likely to cause very serious consequences, and I recommend this investigation especially to those who are interested in the dietary and management of young infants. Dr. R. A. Gibbons[15] relates a most interesting example of fatal and acute purpura hæmorrhagica in a child. The case is a very striking one, and one can hardly doubt on considering it that the condition was due to the pernicious effect of pus in the milk. The child had suffered from severe diarrhœa and was progressing well upon asses' milk until suddenly he became extremely ill with severe epistaxis and all the familiar symptoms of hæmorrhagic purpura. He died after an attack of severe hæmatemesis. About six days previously to his death his mother noticed a thick sediment in the milk, and on inquiry being made the donkey which supplied the milk was found to be suffering from abscess of the udder. Dr. Gibbons states further to me: "I know of two cases in which mammary abscess was developed, and before the suppuration was pronounced the infants were ill. One of these cases, a wet-nurse, I admitted under my own care at the hospital, and she had several abscesses of the mamma."

The influence of blows in causing abscess of the breast is well known. When suppuration occurs in the male breast it is usually due to this cause. Bryant[16] found that of 12 cases 8 were attributed to local pressure or injury, causing extravasation of blood. I have notes of 3 cases where abscess of the male breast followed a kick, a blow from the horn of a cow, and the pressure of a shoemaker's last. In these instances it seems quite plain that a communication is established between an area of tissue containing extravasated blood, the resistance of which is impaired, and the external parts through the torn or injured ducts, and hence organisms may enter and produce injurious effects. Abscess in the breast of infants has been frequently recorded and appears to be largely a preventable malady. The milky exudation which flows from the nipples of some infants is almost entirely due to disintegration of the central cells of the columnar epithelial masses of which the primary gland is formed. When ignorant nurses in these cases pull or rub the nipples a breach of surface is effected by the rupture of a milk duct or abrasion of the integument of the nipple, and, organisms entering, an abscess is the result. In the well-conducted large "lying-in" hospitals of this city abscess of the breast in infants is practically unknown, yet the swelling and hyperæmia associated with secretion of spurious milk are not uncommon and often lead to feelings of alarm in the mind of the medical attendant. A case of mammary abscess in an infant three weeks old is related by Dr. Stephen of Lettercairn.[17] It is said to have been caused by "retention of milk." The child, a female, was sixteen days old when the right breast inflamed, pointed, and was opened, when about an ounce of thick greenish pus escaped. On examination a milky secretion was found issuing from the left breast, which was examined with the microscope and found to resemble the maternal milk except that the latter contained more corpuscles. A case of double mammary abscess in a male infant is related by Dr. Wilks of Ryde.[18]

Attention being drawn to the subject, a number of cases of abscess in infants are recorded by various practitioners.[19] Most observers refer the occurrence of the abscess to the practice prevalent among ignorant nurses of pulling and rubbing the nipples. Dr. Robert Barnes[20] backs up this assertion and states that when he was house surgeon to a lying-in hospital he encountered several cases of abscess in the breasts of infants due to the manipulations of nurses. Numerous other instances may be found in surgical literature where experienced practitioners attribute cases of abscess in infants to this practice.

In cases of swelling and engorgements in the breasts of infants were the attendant content to keep the parts about the nipple scrupulously clean with a very dilute mercurial wash and to apply graduated pressure with cotton-wool and bandage the phenomena of abscess would probably never occur. Suppuration in connexion with new growths in any part of the body is extremely rare, and the same is true of new growths of the breast. Abscesses may, however, be found in the neighbourhood of ulcerating cancer, and the same phenomenon is sometimes observed in other parts; thus

we find abscess of the neck with ulcerating epithelioma and abdominal abscess with ulcerating carcinoma of the intestine. In very exceptional cases the cysts of sarcoma or adenoma may contain pus. Should they be artificially inflamed or inoculated with septic material, as by the introduction of a dirty trocar, suppuration is, of course, not uncommon. In the days when caustics were employed to remove cancers of the mamma, surrounding abscess and cellular inflammation were often enough exemplified. In the year 1867 a patient was treated in St. George's Hospital for scirrhus of the left breast with the chloride of zinc paste inserted in the form of arrows into the diseased mass. The whole breast sloughed out, but severe rigors and fever ensued, and a large abscess formed in the other breast. The patient died apparently from pyæmia. A good instance of abscess of the breast in association with scirrhus is the following. A woman aged seventy-six years was in St. George's Hospital in 1883 with a hard scirrhous cancer growing in the left breast and which had existed for two years. Lately the tumour had ulcerated, the nipple was retracted, and the skin adherent. There was a large abscess stretching from the nipple to the axilla. The abscess was opened and much foul pus evacuated. The tumour and pectoral muscle to which it was adherent were removed. The patient recovered favourably. A single woman aged thirty-three years was in St. George's Hospital in 1889 suffering from a tumour of the left breast. She stated that this had existed for six weeks, but the history was very doubtful. Her mother had died from uterine cancer. The patient had always suffered from a painful and retracted nipple. On examination there was a large, round, tender, movable swelling in the upper part of the left breast and the skin was non-adherent. There were some enlarged axillary glands. At consultation exploratory incision was decided on. This being performed, pus was discovered and the sac of the supposed abscess with the surrounding breast tissue dissected out. It was later discovered that papillary growths were present on the walls of the sac. Thus the case was really one of suppurating cyst. Such instances are exceedingly rare. In the past year I saw my colleague, Mr. Bennett, operate upon a large cystic sarcoma. One of the cysts discharged pus abundantly and there was practically a sinus communicating with a large abscess cavity. This had resulted from a puncture with a lancet made outside the hospital into one of the main cysts in connexion with the growth, allowing the cystic cavities to become septic.

Having thus discussed the probable true pathology of the acute forms of mammary abscess a word may be said as to the position and effects of purulent collections within the gland. In nearly all our text-books the division is made into the supra-mammary, the intra-mammary, and the sub-mammary abscess. As regards the first variety, the pus forms immediately beneath the skin of the areola, and in a considerable number of cases is doubtless due to suppuration in some of the sebaceous structures (glands of Montgomery) which exist in that position. As regards the sub-mammary abscess I may at once state my belief that abscess really beneath the gland is far more rare than is generally believed. I may here state that I have never seen a case of true sub-mammary abscess except as a consequence of caries of the ribs or empyema. I have, indeed, been shown examples where the breast has been pushed forwards as though by pus behind it, but in all of them I have found in operation that the purulent collection has been in the deeper part of the mammary gland itself and not entirely beneath it. In short, it may be said that the majority of mammary abscesses of gravity or significance are found in the substance of the breast itself. Great havoc is wrought by untreated suppuration in the breast. The abscess burrows extensively and in a branching and irregular manner so that numerous pockets or recesses are formed and multiple "pointings" and sinuses may only too readily ensue. A fatal result from septicæmia very rarely occurs, but in severe cases the patient may be invalided for many months and suffer very severely. Sinuses may be so persistent, discharges so profuse, and destruction of the mammary gland so great that amputation has even been thought needful, as in the following case.

A married woman aged forty-four years was in University College Hospital in 1881. She had had five healthy children and then six miscarriages. Beyond this there was no suspicion of syphilis and no symptoms or history of tuberculosis. She had never suckled with the left breast which had been inflamed and tender for about eight weeks. The upper and inner part of the left mamma from the third cartilage to the xiphoid was firm, tender, and lobulated, the skin being red and adherent over low rounded prominences. Three sinuses near the nipple were discharging thin yellow pus from a superficial abscess. The liver and spleen were enlarged, smooth, and not tender. Menstruation was normal. The evening temperature was raised. The gland was described as riddled with sinuses and was amputated under antiseptic conditions, and the wound speedily healed. The gland was indurated, traversed by sinuses with granulating walls, leading to a cavity beneath the breast. The ducts were full of soft caseating material.[21]

In the breast it especially happens that abscesses are prone to become constricted in one part, where the pus has burrowed through a fascia or intra-mammary septum. The abscess then assumes a shape which may well be likened to an hour-glass. This most important variety of mammary abscess is too little noticed in modern times, but was long ago well described by Velpeau under the term "abscès en bouton de chemise."[22] I have seen several examples of this condition. The abscess shows itself as a subcutaneous swelling, and if the usual practice is adopted of making an incision radiating from the nipple the discharge will continue indefinitely: the true explanation being due to the fact that the main bulk of the pus is found deep in the substance of the gland communicating with the collection found under the skin of the areola by a narrow and sometimes sinuous channel of considerable length. I shall refer to this variety of abscess again when speaking of the subject of treatment, and meanwhile I may only point out that the likeness of the shape of the abscess to a shirt button as stated by the French writer is peculiarly appropriate.

I propose next, as briefly as possible, to pass in review the pathological causation of the more chronic varieties of mammary abscess which, though comparatively infrequent, are not less important than the acute on account of the numerous diagnostic difficulties and errors to which they give rise. And first it will be convenient to consider the influence of tubercle in producing abscess of the breast. Sir Astley Cooper noticed long ago the existence of "scrofulous tumours" in the breasts of single women; the skin becomes softened over them and finally gives way with a discharge of thin watery or curdy pus. The axillary glands are prone to share in the mischief, becoming enlarged and slowly suppurating. Dr. Charles A. Power[23] reports a case operated upon by Bull in 1886. This writer finds authentic records of 35 cases. Of these, 34 were in females and 1 in a male. Of the 34 women, 22 were married and 5 were single. In 8 these conditions were not mentioned; 21 of the 22 women had borne children and 6 had suppurative inflammation of the breast, while 3 had had inflammation not going on to suppuration. In 18 the right breast was affected; in 14 the left breast, and in 1 both glands. The youngest patient was seventeen years and the oldest fifty-two years. Excellent examples of this affection are related by Hebb and Shattock in the Transactions of the Pathological Society for 1888, and an extensive bibliographical list is given by Shattock in THE LANCET of June 8th, 1889, which comprises most, if not all, of what has been written regarding the subject up to that date. Payne[24] has related a remarkable example of tuberculous abscess near the nipple of a child who subsequently died from general tuberculosis. The important question of the transmission of tubercle by a mother to her child from the milk was discussed in this case. Most opinions were in favour of the possibility of this, though one observer pointed out that he believed Colles' law held good in tuberculosis as well as in syphilis. Personally, I have met with six cases of tuberculous abscess of the mamma, but I will only quote one of them, which will serve as an example of the others. In June, 1893, I saw at the Hospital for Women and Children in the Waterloo-bridge-road a pale, emaciated, worn woman aged forty-three years who had the scars of old gland disease in her neck and who had lost two children from phthisis. She herself had twice experienced attacks of hæmoptysis and had suffered with the left breast for about twelve months, "a lump" having broken and discharged. On the axillary aspect of the left mamma was a ragged cavity with livid undermined edges. The axillary glands were enlarged and one of them distinctly fluctuated. Close to the abscess cavity the breast was much indurated and

Digitized by Google

thickened. The discharge was thin and watery, but no tubercle bacilli were found therein. The axillary abscesses were opened and the ulcer scraped and dressed with iodoform. It never soundly healed and the woman would not consent to any more radical measures being adopted. As an instance of this affection occurring in a man I may quote the following. The patient, aged thirty-one years, was in the Westminster Hospital under Mr. Macnamara on Sept. 20th, 1893. Six months before admission he had noticed a lump in the left breast, which was painless. No history of syphilis was obtainable, but the man stated he was struck with a bar on the part a year previously. The tumour is described as forming an indolent lump, movable and not affecting the skin; the nipple was normal. There was slight glandular enlargement in the axilla. A considerable portion of the breast was removed with the caseous mass, but the affected glands were apparently left.

It would serve little useful purpose to quote numbers of those cases, for their pathology and clinical significance are very similar to tuberculous maladies occurring elsewhere. The abscess may be singular or multiple, and the surrounding breast substance healthy or more commonly riddled with small cavities containing caseating material. Thus the French writers will divide these cases into disseminated isolated tubercle, confluent tubercle, and "cold" abscess.[25] Practically speaking, tubercle of the breast will seldom or never come before the surgeon until its grosser symptoms are manifest. It is especially important to note that the bacillus is not always found in the discharge and the presence of caseating material on the walls of the abscess and around it is the principal distinguishing sign to the naked eye.

The symptoms of these important abscesses may thus be summarised. They are indolent in progress, forming chronic—and often—hard lumps in the breast of those who commonly exhibit signs of the tuberculous diathesis or have marked hereditary proclivities towards tuberculous disease; the skin is commonly slightly reddened over the centre of the swelling; and finally, when fluctuation occurs and thin, watery pus is evacuated, an unhealthy ulcer with livid, overhanging edges and feeble granulations is generally left. The axillary glands are very often affected, and this, together with the hardness of the swelling in its earlier stages, has probably led to the diagnosis and treatment for cancer being adopted more frequently than surgeons are apt to allow. While exceptionally occurring in very young or in old individuals it may with truth be said that the majority of chronic abscesses of the mammary gland are not tuberculous and their pathology and causation are matters of the highest interest and clinical importance. Typical cases of this nature are found in women forty years of age and upwards in whom lactation has long been in abeyance and in whose cases apparently no known cause can be adduced. I have already stated my belief and quoted a case in point that the true explanation of many of these obscure cases is the entrance of organisms through some slight breach of surface on the nipple or at its base. Another pathological point of great interest and importance as regards the pathology of these abscesses is the frequency with which one finds a history of antecedent abscess or inflammation in the breast, it may be many years before. So frequently do I find this, that one cannot doubt but that many chronic abscesses of the mammary gland are what were well termed by Paget "residual abscesses."[26] We have at present no certain means of knowing how long a time organisms may lie latent within the tissues, to be started into activity by some form of stimulation, and the whole question of the latency of organisms of disease is an untrodden ground rich with interest and importance. Some of the several instances I have seen of chronic abscess arising in a mammary gland, the seat of old-standing suppurative mischief, may now be quoted.

A married woman aged forty-two years was admitted into St. George's Hospital on Aug. 20th, 1888. She had been married twenty-three years and had borne ten children. Her last pregnancy was four years ago. Sixteen years before admission she had an abscess of the right breast, which had burst. Since then she had never been able to suckle with that breast. Six weeks ago, with no apparent cause, the right breast became painful and gradually swelled, and finally another abscess burst in the exact site of the former one. There was a sinus in the breast leading into indurated tissue. These conditions were cured by ordinary treatment. A married woman aged forty years saw me at the Waterloo-bridge-road Hospital for Women on Nov. 25th, 1874. Her right breast had become painful and swollen without any known cause for eight weeks. She had had twelve children and four years ago had two abscesses in the right breast. The scars of the sinuses resulting were still to be seen. Her last child was born four years ago. On examination the right breast was irregularly swollen and just internal to a deeply retracted nipple were two rounded, red, fluctuating swellings, obviously abscesses. These were opened, scraped, and the tube brought out below as will be hereafter explained. The pus contained the staphylococcus aureus in abundance. It is only right to point out that although in a number of instances of chronic abscesses of the breast there is a history of past suppurative affections, yet cases are met with where no such explanation, or, indeed, any rational explanation, is possible. These abscesses may occur in any part of the mammary gland but are commonly deeply seated. They are surrounded by much dense indurated tissue and the contents are thick and inspissated. From time to time surgeons have drawn attention to the extreme similarity between these affections and scirrhous cancer, and even with our modern knowledge diagnostic mistakes between chronic abscess and cancer more frequently occur than surgeons are willing to allow.

The symptoms of acute mammary abscess are so well known that it would be idle for me to attempt to enlarge upon them. Yet cases are related where acute inflamed cancer exactly simulates them. Mr. Howard Marsh, in vol. xxiii. of the St. Bartholomew's Hospital Reports, has recorded an admirable example of this condition. A most remarkable case of inflamed carcinoma simulating abscess was under the care of my colleague (Mr. Dent) at St. George's Hospital in March of this year. The patient was a pale, emaciated, wan-looking, single woman aged thirty-seven years, and her right mamma had been getting swollen and painful for three months. The symptoms of abscess were all exemplified in redness, swelling, heat, and pain, with elasticity and fluctuation, but the pain was "shooting," not "throbbing," in nature and the skin over the swelling showed the appearance of *peau d'orange*. An incision revealed a breaking-down growth with a cavity in its centre full of blood and serum. Microscopically the growth after removal proved to be scirrhus. The diagnostic importance of the symptom of *peau d'orange* was thus shown to be very great. It is otherwise with the chronic variety of mammary abscess. The depth at which these abscesses are situated, the induration of the tissues round them, the frequent co-existence of a retracted nipple, and chronically enlarged axillary glands make the diagnosis from scirrhus impossible without exploratory incision. Nay, even this may mislead. On Aug. 28th, 1894, I saw a spare, healthy-looking woman aged twenty-seven years, a patient of Mr. Hugh Webb of Parson's-green, who was suffering from a tumour of the left breast. She had never been pregnant. She had noticed the occurrence and gradual enlargement of the tumour for about four months. The nipple was deeply retracted and beneath it, incorporated with the breast tissue, was a hard mass, feeling in all respects like a mass of cancer. The axillary glands were not affected. The family history was good. There had never been discharge from the nipple. An exploratory incision was made into the mass and some pus welled up, but the tissue was so dense and bore so exact a resemblance to cancer that it was thought wise to remove the whole breast. The abscess was the size of a small walnut, situated deeply beneath the nipple, and surrounded by hard indurated tissue to the extent of half an inch. Dr. Rolleston kindly examined this tissue with the microscope, and I append his report: "Groups of atrophied and compressed mammary tubes enclosed in well-formed old fibrous tissue ..... sections of the wall of the abscess shewed well-formed fibrous tissue with an irregular lining of small cells, among which there are some traces of hæmorrhage." It is questionable in cases like this whether removal of the breast is or is not the right course to pursue, and upon this most important point opinions may well be divided. The records of every hospital, if carefully perused, will afford instances of confusion between chronic abscess and carcinoma of the mamma, and will exemplify the truth that the precaution of adopting

Digitized by Google

an exploratory incision will alone discriminate between these affections. A series of chronic mammary abscesses simulating cancer are quoted by Reclus,[27] and the same subject is dealt with at length by Castex.[28]

I have intentionally somewhat hurried over the subject of the symptoms of mammary abscess, for they are tolerably well known, and I am anxious to dwell upon some points in connexion with the treatment of the disease which I believe to be of the highest importance. In the first place acute mammary abscess should be a preventable disorder if the medical attendant is careful as to the cleansing of the nipple and of the mouth of the child, and is aware of the importance of attention to the proper care of the nipples previously to marriage. In certain cases of mal-development of the nipples fissures or ulcer will arise and in such abscess may occur even with the best care. I propose to speak of the purely operative treatment of acute abscess of the breast, without ignoring the important accessories of weaning the child, supporting the breast, the administration of various drugs, or expression of the milk by massage and the exhausting pump. The prevention of mammary abscess by expression of milk, and the use of an exhausting bottle to the nipple, is favourably spoken of by Spencer and Beale.[29] The latter also advocates the treatment of mammary abscess by opening with a trocar and cannula, and applying the exhausting bottle to the aperture. While I am ready to admit that this treatment might be applicable to small superficial abscesses, I should hesitate to apply it to deeply-seated collections of pus with loculi in the substance of the gland.

I feel quite sure that the treatment of acute mammary abscess by the method of establishing a free opening anteriorly radiating from the nipple is essentially wrong. It leaves a scar on the front of the breast and, what is of greater importance, it opens the purulent collection in a position the least suitable for drainage. As a consequence many of these cases need several operations until drainage-tubes are seen projecting through various openings and very unsightly scarring results with subsequent deformity and grave interference with the functions of the gland. In a considerable majority of the cases I have been able to collect from the records of St. George's and other hospitals several operations under anæsthetics were often needful. This clearly means inefficient drainage. I will now describe the method of treatment I have found efficacious in several cases, trusting that those who have extensive practice among parturient women will give it their careful consideration. So soon as elasticity and deep fluctuation are evident an incision is made radiating from the nipple just large enough to admit the index-finger of the operator and this is deepened until pus flows. The finger is now passed into the cavity, and in the vast majority of cases it will be found that the end of the digit may be brought fairly near the surface in a dependent position, and this is generally at the thoracic mammary junction. In this situation it may especially be noted that scars are hidden from view. Sometimes the finger passes towards the axillary margin, and occasionally the cavity is so large that a stout dent probe must be used to indicate the deepest part of the abscess. In this situation, the gland being well raised by an assistant, a free opening is to be made, large enough to well evacuate the pus, and the finger being now introduced through this the inferior opening, the operator will be surprised to find that the pus has burrowed about, and is contained in loculi bounded by fibrous septa. It is especially noteworthy that in many cases quite a narrow channel towards the nipple connects the deep abscess with the more superficial collection of pus opened anteriorly, and it will then be clearly understood how inefficient is drainage in the practice of those who are content with a small incision anteriorly in these cases. The remainder of the treatment is obvious; the cavity is well flushed out with whatever agent the operator fancies, and a full-sized tube is introduced from below. The opening made near the nipple is closed with fine horse-hair and painted with collodion. It readily unites with only a faint scar, and the free drainage prevents the possibility of the re-collection of pus and a necessity for further operation. The tube, a large one, can be left in the cavity as long as needful and is slowly shortened and withdrawn. It may seem superfluous to mention that the drainage-tube should be secured with a piece of silk, but the fact of the tube having entered an abscess cavity and having been there retained or only removed by a troublesome operation must not be lost sight of. This accident may readily happen unless special care be taken. The unsightly scar is completely hidden by the position and volume of the gland above.

The treatment of chronic abscess of the breast is a matter of greater difficulty and must ever raise differences of opinion. The importance of exploratory incision has already been raised, and I would here make a statement which may seem exaggerated, but which experience and a perusal of the literature of the subject permit me to positively advance. There is no symptom of scirrhous cancer of the breast which may not be simulated by a chronic abscess enclosed in a dense mass of inflammatory material, and unless exploratory measures are made as a matter of course grave errors of treatment will occasionally arise. The diagnosis of chronic abscess being established one of the first thoughts which should arise is as to the presence or absence of tubercle. The thin and watery nature of the pus with the presence of caseating material in the walls of the abscess is one of the best naked-eyed tests that can be applied. Many writers seem to be in favour of removing the entire breast in cases which appear to be of a tuberculous nature. With reference to this very important point in operative surgery much will depend upon the extent of the disease. In disseminated tubercle, where several abscesses or masses of caseating material are disseminated in the breast, removal of the entire organ, with possibly the axillary glands also, is undoubtedly the right treatment to adopt. With regard to non-tuberculous chronic abscesses there is again no absolute rule. When the abscess is surrounded by tolerably healthy mammary tissue and has moderately thick parietes the free use of the spoon, with scraping and flushing and drainage in a dependent position in the thoracic mammary furrow, will give good results. But if the abscess, as in one of the cases I have related, is enclosed in a dense mass of inflammatory tissue infiltrating the greater part of the breast, and especially if the patient be at the age when scirrhus is frequent, removal of the entire organ is, in my belief, the wiser course to pursue. Regarding this question there is much difference of opinion. It is always most difficult in practice to determine at the moment what is best for the patient, and the operative treatment of chronic abscess of the breast is eminently one for consideration and discussion. I can only assert my belief that breasts are removed too frequently for these affections, and that free drainage in a dependent position with erasion and flushing will negative the necessity for the more serious operation in the vast majority of cases we meet with in practice.

ON THE FORMATION AND STRUCTURE OF DENTAL ENAMEL.[1]

BY J. LEON WILLIAMS, D.D.S. BALTIMORE, L.D.S. R.C.S.I.

ALMOST every anatomist or histologist of note since the time of John Hunter has made some contribution to the subject of this paper. In going over the literature of the theme one is struck by the wide divergence of opinion expressed—a divergence which is as marked and emphatic to-day as it was forty or fifty years ago. Broadly speaking, all who have written on the subject may be separated into two groups or schools: those who have taught that the formation of enamel is effected by direct cell-calcification and those who have claimed that the tissue is produced by a secretion—by the calcification of a cell-product. Between 1850 and 1860 Professor Carpenter was maintaining the former position, and during the same time the late Professor Huxley wrote several papers antagonising this view, and claiming that enamel could not be produced by any conversion of a cellular structure. Curiously enough, his main contention was correct, although founded upon mistaken premisses. In 1848 the late Sir John Tomes delivered a course of lectures in which he taught that enamel-formation is the result of the calcification of the enamel-forming cells. His son, Mr. Charles Tomes, in the last

[1] An abstract of a paper read before the Royal Society, Dec. 12th, 1895.

Digitized by Google

edition of his work on Dental Anatomy, published in 1894, still holds to this opinion, and these views are also shared by Waldeyer, Wedl, and many others. On the other side, Professor Schäfer in England, Professor Spee in Germany, and Dr. Andrews and Dr. Sudduth in America have maintained that the enamel-cells or ameloblasts are not directly calcified, but that they are the active agents in producing the material from which enamel is formed.

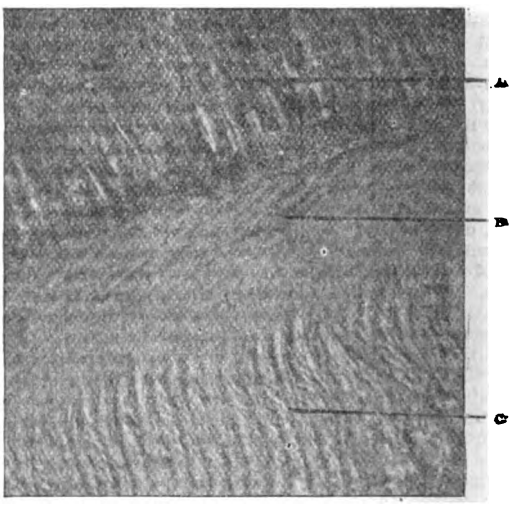
It is not my intention to present a summary of the history of the literature of this subject, and I have mentioned the foregoing names merely to show that the most eminent teachers have held, and still hold, widely different views. This difference, I believe, has largely grown out of relying too closely on one or on a few particular methods of working. I have seen many illustrations of the possibility of drawing contradictory conclusions from appearances presented by different methods of treating tissues, each of these conclusions very probably representing a half truth. Another reason may also be found in the very great difficulties attending the preparation of thin sections of developing teeth with all of the tissues in their normal relations. In deciding, therefore, to reinvestigate the whole field of the development of the teeth I determined at the outset to adopt a large number of methods of working, in the hope that by comparing the results of widely differing treatment I might unravel some of the tangles in which the subject has always been involved. I selected for the commencement of my work embryos of the cat, dog, sheep, cow, hog, and monkey, as well as human embryos of all stages of development. The rodents were also represented by mice, rats, and guinea-pigs. Some of the material was cut while fresh and some immediately after fixing by freezing processes. Other material was fixed and hardened by a great variety of processes and embedded in balsam by the Weil process or decalcified by different acids and embedded in paraffin and celloidin. More than thirty different stains and combinations of stains have been tried, and sections have been mounted in balsam, Farrant's medium, glycerol, sulpho-carbolate of zinc in glycerol (my favourite medium for purposes of study), and other preservatives. As there is but little difference of opinion concerning those earlier stages of tooth development which precede the commencement of the formation of dentine and enamel we need give no further attention to this period than is necessary for an introduction to the subject proper. All students of dental histology are now aware that the teeth are developed from two distinct tissues. The so-called enamel organ is a product of the oral epithelium, while the dentinal germ or papilla is formed in the submucous or dermal tissues, the former being the first to appear.

The first sections cut for these special studies were from the jaw of an embryo lamb at a period just after the commencement of enamel formation. The material was fixed in a saturated aqueous solution of corrosive sublimate, partially decalcified in a weak solution of chromic and nitric acids, and embedded in paraffin. Sections were stained with a modification of the Ehrlich-Biondi fluid. The appearances were different from anything I had before seen. There was no trace of a prismatic character in the partially decalcified enamel, but instead a faint appearance of fibres running parallel with the inner ends of the ameloblasts, with small globular masses irregularly distributed among them.

FIBROUS CHARACTER OF ENAMEL.

With the suggestions which this specimen gave me I prepared some extremely thin sections from the persistently growing incisor of the rat. The enamel rods in the enamel of the rat, as is well known to those who have studied the subject, terminate a little below the surface, leaving on the outside a thin layer of clear and apparently structureless enamel. A partial decalcification of this layer showed a stroma composed of two sets of fibres running in nearly opposite directions, neither direction corresponding with the long axis of the ameloblasts. One set of fibres passes in a somewhat more oblique course than the other and becomes confluent with the ends of the enamel prisms. The other set of fibres sweeps downward on a circular course, crossing the more oblique-running fibres and the enamel prisms nearly at right angles. Sometimes both sets of fibres join and twisting about each other in a rope-like design pass along the course of the enamel prisms (Fig. 1). It is probable that the arrangement of fibres is fairly constant in teeth of the same animals, although differing widely in teeth of different animals; but it is only by cutting sections in a great variety of directions that one at last gets a true picture of the complex arrangement of fibres and rods. Enamel from the teeth of rats and mice shows a more marked fibrous character than any other that I have examined, and the most striking feature of arrangement of the fibre is the interlacing or weaving together of those running in

FIG. 1.



Forming enamel from incisor of rat. × 800. A, Enamel cells. B, Outer fibrous layer of enamel. C, Enamel rods showing twisted fibres.

different directions, like warp and woof in a web. This is very plainly shown in Fig. 2, where the torn edge of the enamel bears a striking resemblance to the effect produced by tearing a woven fabric of any sort.

STRUCTURELESS BASEMENT MEMBRANE OR MEMBRANA PRÆMAFORMATIVA.

By means of selective stains I have been able to demonstrate the existence of a membrane-like structure lying between the ameloblasts and the forming enamel and also between the ameloblasts and the stratum intermedium. It is uncertain whether this structure is identical with the membrana præmaformativa of Raschow, Huxley, and others. Its existence has been disputed by several of the more recent writers upon this subject, but it is plainly shown in Figs. 3, 4, 5, 6, and 7. I suggest that the structure lying between the ameloblasts and the stratum intermedium be called the *outer ameloblastic membrane*, while that which separates the enamel cells from the forming enamel may be known as the *inner ameloblastic membrane*.

THE CELLS OF THE STRATUM INTERMEDIUM.

It has for many years seemed clear to me that the enamel organ, and more especially the cells of the stratum intermedium, should be classed among the true secreting tissues. I am not able to understand how so many good observers have failed to see the intricate plexus of bloodvessels, which is very early developed in this layer of cells. Wedl, Magitot and Legros, Suddoth, and others say that they have uniformly failed to detect a blood-supply within any part of the enamel organ proper. If we examine the evolution of this tissue in the enamel organ of the mouse or the rat its place among glandular structures at once becomes evident. All appearance of round, polygonal, or oblong cells, as usually seen in the stratum intermedium, has entirely disappeared, and in their place we have a highly differentiated secreting tissue. The ameloblasts are surmounted by epithelial papillæ, around and between which is a free distribution of capillary loops. The ameloblasts are seen to be in intimate relation with the papillæ, each ameloblast seeming to have a root-like process which extends into and is lost in the substance of the papilla to which it belongs. The diameter of each papilla is equal to about that of five or six ameloblasts, and each papilla may therefore be said to supply from twenty to twenty-five ameloblasts. Bloodvessels are seen, in both transverse and longitudinal section, everywhere

Digitized by Google

about the papillæ, and we may often observe branches descending to supply the loops which pass round the ends of the papillæ lying next the ameloblasts (Fig. 2).

At the commencement of enamel-formation in the teeth of

the mouse there is but little indication of a special secretory organ, as may be seen by referring to Fig. 4. We see here that the outer ameloblastic membrane is not structureless, but is apparently composed of very fine fibres.

METHOD OF FORMATION OF ENAMEL.

Several observers of distinction, notably Dr. R. R. Andrews and Professor Spee, have described the development of enamel as a process in which the tissue is formed by the deposit of droplets or spherules of calcoglobulin. This view is undoubtedly correct, but, as stated by the writers mentioned, it does not include all the phenomena that may be observed. The ultimate structure of completely formed enamel shows that it is built up by the deposit of bodies

which are of very nearly uniform size. There is, as we shall see, no uniformity in the size of these masses of calcoglobulin, neither is there anything in their structure which corresponds with that of formed enamel; in fact, under the finest lenses that are made they show as highly refractive

masses without definite structure. Although they are usually more numerous at the inner ends of the ameloblasts, next to the forming enamel, they may be seen throughout the entire

Digitized by Google

length of these cells, and I have often seen them lying close up to the membrane which separates the ameloblasts from the stratum intermedium. Occasionally I have espied them when they seemed to be actually in, or emerging from this membrane. Such appearances are shown in Fig. 5. It is possible, and I think highly probable, that this substance, although appearing in the ameloblasts, is really formed in the more specifically secreting cells of this stratum intermedium. These masses probably consist of calcoglobulin, an albumin-like substance holding calcific material in solution. Its function, I believe, is not the building up of the enamel rods as has heretofore been supposed, but the formation of the interprismatic or cement substance which binds the enamel rods together. It is clearly shown in Fig. 6 that the enamel rods are formed by the superposition or continuous deposition of bodies which are spherical when they leave the enamel cells, but by compression or chemical action are more or less charged into a disc-like shape as they take their place in the building of the enamel rods. Thus for the first time we have a clear explanation of the varicose appearance of the rods or prisms in completely formed enamel. Each varicosity of the rods represents one of these globules or disc-like bodies. In the inner portion of enamel next to the dentine the enamel globules usually melt together so completely that their individual form is lost, but as we approach the outer surface of the enamel the rods are clearly seen to be composed of globular or flattened bodies, not completely united, but still connected by calcified plasmic strings. These plasmic strings, of which there are many to each enamel rod, are often seen under a power of from 800 to 1000 diameters to be made up of granules, and these granules, so far as our present powers of observation are concerned, constitute the ultimate structure of enamel.

THE CROSS STRIÆ AND RETZIUS BANDS.

My observations on these points have led me to totally different conclusions from those reached by Professor von Ebner of Vienna. Professor von Ebner regards the striæ of the enamel rods as an artificial appearance produced by the action of acids, and the Retzius bands as due to ground-off or artificial prism ends, and also to imprisoned air or gas contained in minute tubes or canals.

I have clearly demonstrated that the cross striæ are due to the varicose enlargements of the enamel rods and that these varicosities are produced by the successive deposit of globular masses from the enamel cells. The deposit of these bodies is simultaneous over the entire surface of the forming enamel, hence the regularity of the lines of striation and increment. I have further shown that the Retzius bands cannot be due to air or gas in minute canals because there are no such canals in normal human enamel. Neither are these bands due to the ground-off ends of enamel rods, as may be clearly seen from Fig. 8, where the rods are seen to pass through several bands without break in their continuity. The Retzius bands are caused by pigmentary matter in the granules which constitute the ultimate structure of enamel. Completely formed normal human enamel contains no living matter in the sense in which this term is generally understood. There are consequently no nutritive changes in enamel after it is once formed.

George-street, W.

THE FRENCH HOSPITAL.—The twenty-eighth annual dinner in aid of the funds of the French Hospital and Dispensary in London was held at the Hôtel Métropole on April 25th. The chair was taken by the French Chargé d'Affaires (M. Léon Geoffray), who was supported by, among others, the Lord Mayor, the Swiss Minister, the Italian Ambassador, Sir William MacCormac, Dr. L. Vintras, Dr. J. Keser, and Mr. E. Rüffer (honorary secretary). Subscriptions and donations amounting to nearly £2500 were announced.

REMARKS ON A CASE OF SPLENECTOMY, WITH OBSERVATIONS ON THE CONDITION OF THE BLOOD BEFORE AND AFTER OPERATION.

BY C. J. BOND, F.R.C.S. ENG.,
HONORARY SURGEON TO THE LEICESTER INFIRMARY.

WHILE our knowledge of the function of the spleen as far as regards its relation to the corpuscular elements of the blood is somewhat fragmentary, still evidence has accumulated latterly[1] which points strongly to the very important share the spleen takes in the breaking up of the red corpuscles. It is in order to emphasise this point that I am induced to publish the following remarks.

It seems pretty clear from the experience of several observers, Gibson and others, that the effect of removal of the spleen in dogs is to produce at first a diminution in the number of red corpuscles and an increase, both relative and absolute, in the number of white corpuscles; this condition reaches its maximum in a few weeks, and then, owing probably to the fact that other organs concerned in blood metabolism, such as the marrow and lymph glands, take on compensatory action, the normal proportion of red to white corpuscles is re-established in a few months. In the case of man, although numerous cases of splenectomy have been recorded, there are very few in which the blood condition both before and after operation has been accurately noted. In Crédé's case the immediate effect of removal was an increase in leucocytes, but the blood reached its normal state later. In this case, however, the spleen was cystic, and it is very important to bear in mind that in experiments on animals it is a physiologically healthy organ which is removed. So, too, in those cases in man in which the spleen has been removed for cystic disease, the organ is not probably in that active pathological condition as regards blood metabolism, that it is in other cases of splenic hypertrophy and splenic lymphadenoma, consequently the effect on the blood of removal of the organ is likely to be very different in the two classes of cases. With these few preliminary observations I will shortly narrate the notes of the case and then offer one or two remarks on the effect of removal of the spleen on the blood.

A married woman aged thirty-five years, having two children, the youngest aged six years, was strong and healthy until two years ago, when, without any apparent cause, her health began gradually to deteriorate and she first noticed a swelling in the left hypochondrium. During these two years she has gradually lost strength and flesh and become more anæmic, and has suffered, too, from occasional attacks of vomiting, until during the last fortnight the vomiting has been excessive and the asthenia very great. There was a large movable mass in the left side, having all the characters of an enlarged spleen; it was very movable, so that the sharp notched anterior margin could be turned right over and made to lie in the left flank, and it was, I think, probable that this extreme mobility, by causing stretching of the gastro-splenic omentum, may have been the chief cause of the vomiting. The temperature was normal, the urine healthy but somewhat deeply pigmented, with occasional deposit of urates. After a few twenty-grain doses of calcium chloride on the three previous days the spleen was removed on March 27th, 1895, four days later. A median incision was made and the enlarged organ delivered lower end first; owing to its extreme mobility and the absence of adhesions this was not difficult. The pedicle was wide and contained some inches of the tail of the pancreas, which easily came outside the abdomen. The splenic artery, enormously enlarged, was first ligatured separately and the rest of the splenic mesentery was ligatured in several portions and the organ removed. The abdominal wound showed a tendency to bleed unduly and the blood appeared brighter and more arterial than usual; after swabbing with hot hazeline it was sutured and no further hæmorrhage occurred. Recovery from the surgical point of view—that is, as far as the wound was concerned—was uneventful. At the end of the first week, after a week's subnormal temperature, the patient complained of considerable pain in the region of the liver and the temperature ran up to 101°F.; it came down, however, in a few days, but ran up again to 103° a fortnight later, and for three days continued of remittent type, with morning remissions, again becoming normal on the third day. I have noticed these irregular rises of temperature, having no surgical cause, in two other cases of splenectomy, and, indeed, in patients who are suffering from splenic enlargement with or without leucocythæmia, the temperature line, even when normal or subnormal, shows the evening rise and morning remission; it may, I think, probably depend on the blood condition and requires further investigation.

The effect of the removal of the organ on the blood may next be considered. The blood was examined three days before operation; at that time the red corpuscles numbered only 3,000,000 per c.m. and the white about 1 to 250 red, and the hæmoglobin was only 50 per cent. of the normal quantity. At that time the patient was on a generous diet and small doses of arsenic and iron. Seven days after removal, the patient having been on the very low diet usual for the first few days after abdominal section, the red corpuscles numbered 6,000,000 per c.m. and the white 1 to 250 red, and the hæmoglobin had risen to 80 per cent. The blood was now examined at intervals of about a week; the excessive increase of red corpuscles was not maintained, but fell on April 11th to 5,800,000, on April 21st to 5,200,300, but rose again on April 28th (which date coincided with the febrile attack) to 6,000,000, but fell again, till on May 28th it was 4,120,000. The white corpuscles showed a very slight progressive increase and the hæmoglobin fell after the first week from 80 to 70 per cent. and remained at about 65 per cent. of the normal. The marked change in the patient's appearance after the first week, from pallor to a florid complexion was very striking, and when last seen on June 8th the appearance was maintained; she expressed herself as feeling well, though still weak; the urine was now and had been pale since the operation. The spleen after removal and when drained of blood weighed 1 lb., was uniformly enlarged, of a dark-blue colour, and on microscopical examination showed the appearance of simple hypertrophy—that is, enormous increase of the pulp tissue or reticular structure crowded with lymphocytes. Besides the changes in the corpuscular elements in the blood mentioned above, there were other changes. A specimen of blood both before and after operation when examined immediately after withdrawal showed a considerable number of masses of granular protoplasm like islands in the plasma. On staining thin films of blood coagulated by heat immediately on withdrawal, with Grubler's esosin hæmatoxyline glycerine stain, these irregular protoplasmic masses stained deeply with hæmatoxyline contrasting strongly with the esosin coloured red corpuscles. As to the nature of these bodies, knowing that other observers have described the appearance of granular bodies in the blood, which have been really a post-mortem change and due to aggregation of blood platelets and other causes, it seemed likely that such might be their origin in this case. The fact that they were present in a film of blood heated on a cover glass immediately on withdrawal shows that the change must occur very rapidly. In order, however, to decide this I first examined the blood by pricking the finger through a drop of Hayem's fluid, and allowing the blood to run directly from the vessels into that fluid as practised by Hayem, but I found that these granular masses were still present as such in the liquid. I found, however, when using osmic acid (2 per cent.) instead of Hayem's fluid, that they were not present, as such, in the blood as it left the vessels, but rather an increase of small disc-like granular bodies exactly resembling the figures of Hayem's blood platelets, fixed, no doubt, by the osmic acid in the form in which they circulate in the vessels. An examination of the blood of other patients suffering from other diseases was now undertaken, and while granular masses were occasionally found in many of the diseases accompanied with high temperature especially of the infective type, in which there was increased activity of the blood and lymph organs, I found them especially abundant in a bad case of phthisis in the last stage with a very marked hectic temperature with an evening rise of 103·5°. Here, too, they were absent in the blood received into the osmic acid solution, and instead was found a marked increase in the blood platelets as compared with normal blood. The same masses were found with the same antecedent increase in blood-plates in a case of splenic leucocythæmia,

[1] See papers by Dr. Hunter and Dr. Auld on Hæmatogenous Jaundice. Brit. Med. Jour., Dec. 3rd, 1892, and Jan. 18th, 1896.

Digitized by Google

but in a very much less marked degree, and in this case the very numerous leucocytes were of the large, faintly granular kind with dividing nuclei, and the small, deeply granular lymphocytes, whereas in the case of splenectomy the few leucocytes were like those found in the normal blood. It is also interesting to note that the same granular masses were found to a very excessive extent in a patient in whom the spleen had been removed by Mr. Marriott four months previously. The organ is now in the museum of the Royal College of Surgeons of England, and on microscopic examination showed the same character of hypertrophy together with numerous collections of large multinucleated cells like giant cells.[2] In this case there was no leucocythæmia and not much anæmia, but there was a very marked tendency to hæmorrhage; and, further, I found that these granular masses were practically absent from the blood of a patient when examined fifteen months after removal of the spleen for cystic disease also by Mr. Marriott.

Such then are the facts as far as ascertained. Before drawing any inferences from these as to any function the spleen may have in blood metabolism it may be well to call to mind for a moment the various views held as to the physiology of the normal spleen. It is supposed that the spleen in man takes some share in the retrogressive changes in the red corpuscles, in some way tending to dissociate the hæmoglobin from the effete corpuscle, and thus prepare the way for the further change—the conversion of hæmoglobin into bilirubin which occurs in the liver (Foster). It is held that the spleen, as a part of the lymph gland system, produces leucocytes which are thus added to the blood. It is further held that the spleen produces red corpuscles either by the deposition of hæmoglobin in the large cells of the spleen pulp, or, as held by Virchow, that it converts the leucocytes into the hæmoglobin-holding or red corpuscles during their slow passage through the pulp tissue, and that the essential factor in the disease splenic leucocythæmia is a failure to bring about the conversion of white into red corpuscles. Among these various suppositions it seems clear that in the evidence derived from pathological investigation, as in that derived from experiments on animals, it is very difficult to isolate, as it were, the spleen from the rest of the organs, lymph glands, bone marrow, &c., concerned in blood metabolism, and to apportion the exact amount and kind of function to the spleen which it really possesses. The fact that in the case of splenectomy after removal of a hypertrophied organ, the red corpuscles doubled in number in one week after operation, other things remaining the same, is pretty clear evidence, I think, that the spleen in this case was previously to removal actually engaged in the destruction of the red corpuscles.

The next point is the presence in the blood of the granular masses which are probably not present in the circulating blood, which have for their antecedents an increased number of blood platelets. The masses are so large that it is somewhat difficult to understand how they can be formed by the aggregation of numbers of blood-plates only, and it looks as if each aggregation of platelets was a focus from which at the moment of withdrawal of the blood some effect was produced on the plasma around, causing it to become granular and to take the hæmotoxylin stain. The fact that these masses, with their antecedent increase in number of platelets, gradually increase after splenectomy, and were also present in a marked degree in one patient four months after removal of the spleen, is clear proof that the blood-plates are not formed entirely or even chiefly in the spleen. The further fact that this increase of blood-plates is present together with a marked tendency to hæmorrhage is a matter of peculiarity and of interest, because it has been strongly held by Hayem and Osler, and others that the blood-plates are one of the determining factors in causing coagulation of the blood.

Finally, it is, I think, becoming more evident that these different cases of splenic diseases, varying as they do in their clinical character, in the degree of anæmia, and in the presence or absence of leucocythæmia, each have a different pathology; and that in many cases the disease is a general one affecting the whole system of blood-forming organs, while in others the spleen itself is the organ alone involved, and it is, of course, in this latter class that the operation of splenectomy holds out the best prospect of success.

Leicester.

[2] There is evidence pointing to this being a tuberculous spleen.

A RECORD OF

THE INFECTIOUS DISEASES OCCURRING AMONGST 400 ADOLESCENTS DURING A PERIOD OF TWENTY-FIVE YEARS.

BY CLEMENT DUKES, M.D., B.S. LOND.,
PHYSICIAN TO RUGBY SCHOOL AND SENIOR PHYSICIAN TO RUGBY HOSPITAL.

THE following record of the infectious diseases occurring amongst a large number of adolescents during a period of twenty-five years will be of interest to those who have the welfare of the young at heart during the period of education. There can be no question of the fact that the amount of illness amongst the young is a sure index of the appropriateness or otherwise of their surroundings. And, further, a trivial infectious illness assumes importance in schools in proportion to the number of persons it obtains opportunity of infecting. As a class zymotic diseases are fostered where organic matters, inclusive of animal exhalations, are undergoing decomposition—in fact, these conditions form a fertile soil in which disease bacteria as well as putrefactive bacteria can flourish. They vary in amount and in frequency to an enormous extent in different schools. In some they appear to be regarded as necessary evils and no attempt is made to diminish their number; in others they are encouraged owing to a damp situation causing an absence of vigorous health; in others by reason of facilities for infection, owing to the schools being situated in towns; in others, again, in consequence of children being crowded together in barracks by hundreds instead of in houses by tens; and in others, on account of their faulty sanitary arrangements or by reason of an impure water-supply. When set going in a school illness of this class is multiplied by imperfect medical arrangements, often of the most primitive description, so that infected children are not immediately and completely isolated from the healthy—in fact, in a large proportion of instances pupils suffering from many of the zymotic diseases are allowed to remain and be treated in the boarding houses with those who are not infected. Schools will never be exempt from infectious illnesses until we are able to prevent them by protective inoculations, but they should be under some effective control. This can be achieved by preventing overcrowding, remedying faulty drains, removing refuse heaps, providing a good water-supply, and sufficient and wholesome food. I venture to place this record before the profession, for it indicates what can be done where a school is healthily situated, where sanitary necessities are not ignored, where the provision for sickness somewhat approaches an ideal standard, and where unceasing care is bestowed upon the minutest details in the medical arrangements. At the present time no case of accident or sickness of any kind is treated in boarding-houses, but in every case of unfitness for schoolwork which requires detention for more than a few hours the patient is removed for treatment to the sanatorium, where the proportion of sick beds should be 10 per cent. This must be the minimum number, and to render them sufficient the greatest pains must be taken to isolate the first cases of zymotic diseases and to quarantine those that are suspicious or have even been in close contact with the first case, for without this caution they are totally inadequate and 15 per cent. is imperative. Unless this care is exercised large schools must have their cases of infectious illness by the hundred. It must be borne in mind that, owing to the increased solicitude expended upon children in the nursery in the prevention of illness, a far larger proportion enter upon school life without having passed through the ordinary infectious illnesses which were formerly considered incidental to early childhood, to the infinite gain of the children. For, consider for one moment the mortality of whooping-cough and measles in children under two years of age, while at the school age it is practically *nil*; and in the case of scarlet fever it is 4 per cent. at the school age and 26 per cent. in children under two years of age. The following tables are sufficiently explicit to speak for themselves. I append a few notes of comment upon some points connected with them.

Influenza.—Before the influenza reached Rugby in 1890 it was very prevalent and fatal in various parts of the country, and the headmaster called upon me to discuss the question

Digitized by Google

of reassembling the school in January. Some schools had already given out that they would not assemble. I was unable to advise a resort to this plan and we met as usual. I had never seen a case of influenza, but from watching the published accounts it was quite evident that it mainly spread from patient to patient, as was conspicuous in the House of Commons. I therefore resolved to treat it as one of the ordinary zymotic diseases and isolated every case as it arose, however slight—quarantining on mere suspicion also—for a minimum period of ten days and then disinfected thoroughly before permitting a return to school. The result was that only 16·25 per cent. fell with it in that year, while another school with which I am acquainted and which did not follow this plan had 96 per cent. fall. In 1893, when we had the largest number, by still pursuing this method only 29·5 per cent. were affected. In the six years of the epidemic, with a total number of cases of 431, there was only one death, which arose from cerebro-spinal meningitis.

Epidemic roseola.—This disease is usually, most unfortunately, called "German measles" and is so frequently confused with English measles that it entails endless trouble and anxiety. It spreads largely owing to ill-defined cases. For instance, some cases present merely *pink eyes* and no rash, and are consequently frequently not isolated, so that while they infect schoolfellows they are themselves protected from a subsequent attack. Others have only the subcutaneous lymphatic glands enlarged in the groin, in the armpit, and in the side of the neck. They have no eruption and yet they spread it in the same way.

Mumps.—It is still insufficiently recognised that the orchitis of mumps, as I pointed out in THE LANCET of Oct. 29th, 1881, when it *follows* parotitis (instead of taking its place, as it occasionally does) invariably arises on the eighth day of mumps and never occurs if the patient is kept in bed over the eight days.

Ophthalmia.—Previously to 1875 these cases were not isolated, but were treated in the boarding-houses, so that I have no record of them; since then every case has been isolated as carefully and as strictly as if it were scarlet fever. It is evidently a germ disease which occurs in epidemic form from time to time, obeying the same laws as all classes of zymotic diseases, and having, where hygienic conditions are as they should be, its period of quiescence. In 1893 it was rife all over the country and I was consulted concerning it by several schools. Like all the zymotic diseases of which I am speaking it is mainly a disease of the young and, as a rule, leaves the adult severely alone. For the growth of all kinds of bacteria two things are essential—the germs themselves and a suitable soil for their germination. Without the latter, while the diseases they occasion may occur, they fail to develop luxuriantly and so are comparatively innocuous and do not spread, but only affect some peculiarly susceptible individuals. Woe betide, however, the assemblage of the young where unsanitary conditions are in force. For instance, the advent of cholera in a clean neighbourhood causes little anxiety, while where filthy conditions are rampant it decimates the population. Typhus fever, so prevalent in former years in our gaols as to receive the name of "gaol fever," saved the judges much trouble (where it did not kill them) by otherwise disposing of the prisoners. The germs found the most suitable soil in the appalling state of our prisons, whereas now, owing to their improved hygienic conditions, the germs have not a chance to grow and the disease is practically unknown in them. The germs of ophthalmia have found a similarly suitable soil in the State schools, as has been recently revealed by the commission of inquiry into the condition of the metropolitan pauper schools, where the children are apparently as grossly neglected in all sanitary precautions as were our prisoners in the sixteenth century. Its prevalence is the surest test of unsanitary conditions where the young are concerned, especially the want of soap and water and fresh air. Wherever these are absent in relation to the young there ophthalmia and impetigo are sure to be found.

The need of fresh air for children is mostly felt in the dormitories, where nine or ten hours are continuously spent

in a more or less close atmosphere, varying according to the cubic space and ventilation provided. Some time since I had occasion to visit a school bedroom where five children were sleeping in the cubic space appropriate for three. The stench was so horrible that I retired as expeditiou ly and as gracefully as I could. I knew that by-and-by I should see the effects of this, and sure as fate one of the occupants developed ophthalmia, with subsequently granular lids, which took me thirty-three days to cure, and this with a keen insight into the cause, with an unlimited supply of air indoors, with six hours a day out of doors, with an unlimited and unquestioned food-supply, and with an able and willing nurse at my command with ample time at her disposal. Yet all the circumstances of life were as healthy as could be wished, with the exception of the deficient ration of air. If this difficulty arises where such facilities are possible it is no wonder that it is incurable and that children so frequently become blind where they are overcrowded or where there are insufficient attendants to carry out the nursing. It is hopeless to attempt to prevent the spread of ophthalmia in any school until it is fully recognised that it is as loathsome to retake our gaseous emanations into the lungs as it would be to insert our liquid and solid excretions into the stomach. Yet these pauper children in State schools rebreathe over and over again their prebreathed air, with the natural result. When they receive their due sanitarily ophthalmia, except seasonal sporadic cases, will become as extinct in these schools as gaol fever is in prisons, for it arises from similar faults and is a disease of the overcrowding of children as typhus fever is of adults.

TABLE III, *showing the Average Number of Cases of Infectious Illness occurring amongst 400 Adolescents during a Period of Twenty-five Years from Jan 1st, 1871, to Dec 31st, 1895.*

Name of zymotic disease.	Total number of cases in 25 years.	Average number of cases per annum.	Per cent. per annum.
Influenza	431	17 24	4·25
Measles	368	14·72	3·68
Epidemic roseola	275	11 00	2 75
Mumps	198	7·81	1·96
Ophthalmia	179	7 16	1·79
Chicken-pox	92	3 68	0 92
Scarlet fever	71	2·84	0 72
Whooping-cough	32	1·28	0·32
Ringworm	22	0·88	0·22
Typhoid fever	4	0 16	0·04
Diphtheria	3	0·12	0·03
Erysipelas of head and face	1	0·04	0·01
Smal.-pox	1	0·04	0·01
Total number of all cases of infectious illness among 400 adolescents during 25 years	1675	67 00	16 70

Moreover, there is not a month in the year in which the germs of ophthalmia are not on the war-path. The only months where none are recorded in Table I. are those of the vacations. It will be observed that the largest number of cases has occurred in June, and also, as shown in Table II, the largest number occurred in one of the sunniest years, 1893, though in another sunny year, 1887, there were comparatively few. I can only account for this by those cases which arise from exposure to strong sunlight at cricket in caps which afford no shade for the eyes. The plan seems to me exceedingly injudicious not only from the eye but from the cricket point of view, for strong sunlight in the unshaded eyes causes the lids to be half closed to shield them from the glare, vision is not so acute, and from time to time it prevents cricket altogether through causing granular lids. It may be said that these, possibly sun cases, are not similar to those I have been discussing. This may be true. I do not profess to have arrived at a solution of the difficulty; but I do know this, that, whatever the cause, the effect is much the same—granular lids in spite of urgent and hygienic treatment such as I have described above. There is another point about ophthalmia which I am at present unable to explain—many of the cases are accompanied by albuminuria. The gist of the whole matter is this, that notwithstanding the greatest care, the provision of hygienic surroundings, and even of 800 cubic feet for dormitories, sporadic cases of ophthalmia will arise where the young are congregated together. What happens when these essentials for health are not in force has been revealed by the commission above referred to.

Diphtheria.—It will be of interest to note that the dates of the two cases which occurred in 1883 were June 19th and September 26th.

Small-pox.—This one case occurred in the severe epidemic of 1871–72. As boys are now re-vaccinated, and have been since 1873, on entering the school it is scarcely probable that another case will have to be recorded.

Rugby.

THE VACCINATION LAWS AND THEIR AMENDMENT.

BY P. CALDWELL SMITH, M.A., M.D. GLASG., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH FOR THE PARISH OF WANDSWORTH.

THE principal Acts of Parliament in force relating to vaccination are (1) the Vaccination Act of 1867 and (2) the Vaccination Act of 1871. Previously to 1867 at least three Acts had been passed—one in 1840 entitled "An Act to Extend the Practice of Vaccination"—a purely optional Act; a second in 1853 making vaccination compulsory; and a third in 1858 entitled "An Act for Vesting in the Privy Council certain Powers for the Protection of the Public Health." The 1853 Act was not, however, efficiently enforced. In the 1840 Act inoculation or otherwise producing small-pox was forbidden under a penalty of one month's imprisonment. The Act of 1867 consolidated and amended all the laws relating to vaccination. This Act came into force on Jan. 1st, 1868, and although amended in certain clauses by the Act of 1871 is still called the principal Act dealing with vaccination. A recapitulation of the more important clauses in the Act is necessary to show that, although it is in itself an admirable Act, the method adopted for securing efficient vaccination has, through non-enforcement of some of the clauses, not proved so successful as was at one time anticipated. By this Act, in addition to the payments from the guardians, an allowance was to be given at a rate not exceeding 1*s.* for each child vaccinated. The fee payable for vaccination within one mile from the vaccinator's residence was not to be less than 1*s.* 6*d.*, over one and under two miles not less than 2*s.*, and over two miles not less than 3*s.* Revaccination was to be paid at the rate of two thirds of the fee payable in cases of primary vaccination. The parent was to see that his child was vaccinated within three months. Provision was also made for the inspection of the child after vaccination, for certificates of unfitness, and for insusceptibility. In this Act the certificate of successful vaccination was to be sent to the registrar and a duplicate to be given to the parent. If the vaccination were performed by a medical practitioner other than the public vaccinator the parent had to transmit the certificate to the registrar of the district. Vaccination or surgical or medical assistance incidental to vaccination by the public vaccinator was not to be considered as parochial relief, alms, or charitable allowance, and no such parent or person was to be deprived of any right or privilege or subject to any disqualification. The guardians half yearly were to revise the list of unvaccinated, and it is distinctly stated that they shall cause proceedings to be taken against persons in default. This clause has, as we well know, not been carried out by a large number of boards of guardians in England. In the report of the medical officer to the Local Government Board for 1890 the number of children not finally accounted for, including postponed cases, stated as percentage of total births, was for England and Wales 11·3, while in the county of Bedford it was 30, in Leicester 52·9, and in Northampton 43·6. In the metropolis the largest percentages were in Bethnal-green 30·6, Greenwich 32·3, and Hackney 26·6. In the various unions in England the highest percentages were in Luton (Bedford) 72·5, Falmouth 46·5, Weymouth 28·3, Gloucester 83 2, St. Albans 32·8, Tonbridge 25·3, Oldham 74·4, Barrow-on-Soar (Leicester) 67·2, Leicester 78·7, Loughborough (Leicester) 61·4, King's Lynn 40·2, Kettering 53·3,

Digitized by Google

69·6, and Keighley 80·1. To sanitarians these figures are of exceptional interest, as in these localities small-pox if once introduced tends to spread with rapidity and is a source of danger to the whole of the country. We have only to single out one which has been brought into prominence within the last few weeks—viz., Gloucester. In 1890 the percentage of unvaccinated children to births in that year was 83·2, and there is good reason for the belief that the percentage had not diminished but rather increased in the following years. Over 80 per cent., then, of the children under five years must have been unvaccinated, and we know that among these small-pox spreads with great rapidity and is exceptionally fatal. What has happened there is likely to happen in any unvaccinated or badly vaccinated community, although in the latter the age incidence may be altered.

Another clause in the 1867 Act is worthy of noting—viz., clause 28, which is to the effect that guardians may pay all expenses in working this Act, and in or about inquiries and reports as to the state of small-pox and vaccination in their union or parish, and in taking measures to prevent the spread of small-pox and to promote vaccination upon any actual or expected outbreak. Very few, if any, boards of guardians in England have taken advantage of the clause. It is generally left to the health officer to carry out these inquiries, and more especially has this been the case since the notification of small-pox has been enforced. The 1871 Act principally dealt with the appointment and duties of the vaccination officer, and also that the lists of births and of deaths of infants under twelve months were to be transmitted once at least in each month to such officer. In this Act also a clause was inserted imposing a penalty on the parent or guardian for preventing the public vaccinator from taking lymph from children vaccinated by him. These, in short, are the main provisions of the Acts in force, and after nearly thirty years most sanitarians are of opinion that a change in administration is necessary. When the 1867 Act was passed the laws relating to public health were in their infancy, and the 1875 Public Health Act, not to speak of the more extended 1891 London Act, was not dreamt of. The prevention of all other infectious diseases, small-pox included, is one of the duties of the health officer, and no one doubts that vaccination and revaccination constitute *the*—I would almost say *the only*—means of preventing small-pox. The transference of all powers in regard to vaccination from the boards of guardians to the sanitary authorities is therefore necessary. The advantages of this are obvious. It may reasonably be asked, Have the public any guarantee that these duties would be carried out any better under the sanitary authority? One thing to be said in answer to this is that every sanitary authority has an official who is, or ought to be, capable of directly advising them in all matters relating to vaccination, while under the present system the guardians have not. In nearly all recent epidemics, whether extensive or not, it is the sanitary authority that has always taken the initiative in stamping out the disease, and if such authority had the direct control of vaccination its officials would have immediate cognisance of those persons and localities most likely to be affected.

The abolition of the office of public vaccinator would certainly meet with very strong opposition, but I have for a long time held the opinion that public vaccination is the cause of a very great deal of the objection to vaccination. If vaccination is performed privately it is almost certain that, with due precautions, it would be more general and that the percentage of unvaccinated children would very largely diminish. Each medical practitioner would be supplied by the sanitary authority with a numbered form, the details of which will shortly be considered, and when a child had been successfully vaccinated this form would be transmitted to the medical officer of health. At present the public vaccinators vaccinate, roughly speaking, about two-thirds of all the children vaccinated. That they do their work well no one will deny, but the system adopted is out of date and cumbrous, whereas this system would simplify matters very much. When the Infectious Disease Notification Act was passed some medical men prophesied that it would never work and stated many objections to the Act. Experience has shown that these objections were groundless, and speaking from my own experience the Act is carried out economically, quickly, and with little or no friction between the medical attendant and the officials. It might be said that it throws an additional burden on the general practitioner, but I do not think this Northampton 74·6, Banbury 43·1, Eastbourne 65·1, Halifax burden will prove a heavy one, and, besides, his additional work will be remunerated at a fair rate. Each general practitioner becomes practically a public vaccinator, and as long as the form is filled up conscientiously and the instructions thereon carried out it will be immaterial as to whether the vaccinator performs the operation privately or at his surgery. It is the experience of every general practitioner that he does not vaccinate on the average more than one-third of the children whose mothers were attended by him in their confinement. By this system he would probably vaccinate all, or at least all who were still his patients. Again, revaccinations ought to be paid on the same scale as primary vaccinations, and should public opinion become more educated as to the necessity of this the general practitioner will secure a sure though small addition to his income. This will be secured without any great addition to the rates, as if the profession at large would be satisfied with a moderate fee the money now spent in carrying out the Vaccination Acts would be almost sufficient.

Another factor to be considered is the personal influence of the general practitioner. The respectable working class, to which class the larger proportion of unvaccinated children belong, would be more readily influenced by the advice of their private medical attendant in this matter, and they likewise believe, whether rightly or wrongly, that their own medical man takes more pains in the selection of the lymph used. They could also be more readily brought to realise the enormous benefit, both physically and financially, to be derived from efficient vaccination. Parents much prefer taking their children to their own private medical attendant to be vaccinated, and it is the experience of most medical men that it is not among the parents of those children vaccinated by them that the objection to the operation of vaccination is strongest.

In the next proposed amendment no one, not even the vaccination officer himself, can take offence, as under the present Act his position is a precarious one, and one not at all well remunerated. It may be said that the system of payment by results is a very logical one, but in a matter of this kind it is time, I think, that the system were altered In parishes and districts where the vaccination officer devotes all his time to these duties, and these districts are few, only a simple transfer would be necessary, but in other districts, though not in all these latter, the work might be done by the present sanitary staff. That this is possible is open to discussion, but judging from the thorough knowledge which the sanitary inspectors of the parish of Wandsworth possess of all the various duties which fall to them, I personally would have no hesitation in saying that the duties of vaccination officers could without difficulty be added to their existing duties, and that without lessening the thoroughness of their work under the Public Health Act. In most parishes an increase in the clerical staff would be necessary, but this would not be a serious item, and the services of this official could easily be utilised by the health officer for other clerical work.

The next proposed amendment is one which I would not strongly insist on, but we have the experience of the northern portion of this island to guide us in this matter. In Scotland the limit has always been six months, and there the objection to vaccination is not nearly so pronounced as in England. After twelve years' experience in the north I can speak with certainty on the point and can assert that in all these years I only met with one pronounced anti-vaccinationist. General statements are not, however, so convincing as actual figures, and if we look at the returns of the Registrar-General for Scotland for 1889 and 1890, which are the latest reports in my possession, we find that in 1889 122,847 births were registered, and 3226 of these were unaccounted for—a percentage of 2 63. In the county of Lanark, the most populous county in Scotland, this percentage was 2·5 nearly. In 1890 the percentage for all Scotland was 2·48. Compare this with the returns for England, where the proportion of cases unaccounted for was 9 4 per cent. and for the metropolis 12·2 per cent., excluding postponed cases. The later returns for England, and especially for the metropolis, show a decided increase. In 1891, the latest complete return, the percentages were 14·7 in the metropolis and 11·4 in the rest of England. This is largely explained by the apathy of boards of guardians consequent on the long-delayed report of the Royal Commission on

Digitized by Google

Vaccination. The following table shows the percentages for the years 1880–1890:—

Percentage of Births "Unaccounted for."

Year.	Metropolis.	Rest of England.	Scotland.
1880	7·0	4·5	1 89
1881	5·7	4·3	2·05
1882	6·6	4·5	2·09
1883	6·5	4·9	1·97
1884	6 8	5·3	2·19
1885	7·0	5·5	2·29
1886	7·8	6·1	2·39
1887	9·0	6·7	2 45
1888	10·3	8·2	2·51
1889	11·6	9·6	2·63
1890	13·9	10·9	2·48

One reason for proposing this amendment is that some parents have a strong objection to the vaccination of their children at such a tender age, and not because of their non-belief in its efficacy as a preventive of small-pox. This objection is, from a parent's point of view, a reasonable one; and if, as can be shown in the case of Scotland, the spread of small-pox has not been influenced by this cause alone, and that some objectors to the operation would be silenced, the extended limit might be included among these amendments. From the medical aspect also it might be contended that this extended limit is desirable. I am sure it is the experience of many of us that infantile eczema frequently begins between three and six months, and some of us may have had the unpleasant experience of having been told by parents that such eczema was due to vaccination. This would in some, though not in all, instances be avoided by the extended limit. Any change which is to be made in the vaccination laws must allow for popular opinion, and this extended limit is one which has been frequently put forward by parents who do not on principle object to vaccination. The certificate of successful vaccination is, when filled up, to be sent to the medical officer of health of the district or parish where the child was registered. At present the vaccination forms have a postage stamp affixed to them and there is no reason why the present practice should not be continued. This change would be a very great advance, as all children could be accounted for except those who died before vaccination. Under the present law many children, owing to their parents' peripatetic habits, escape vaccination, and the vaccination officer of the parish in which the child was born loses all trace of its whereabouts. In the parish of Wandsworth for the year 1893 1606 births were registered, and of these 153 had removed to districts unknown and only 3 to districts known to the vaccination officer. The majority of these unvaccinated children would sooner or later be detected by the sanitary officials in their ordinary house-to-house visitation and ordered to be vaccinated. In this case the certificate would necessarily be forthcoming. It would not be a difficult matter to train the present sanitary staff to recognise vaccine cicatrices, and the presence of these cicatrices would be sufficient proof that the child had been vaccinated, when such children had been registered in other parishes.

The form of certificate is one of the most important amendments proposed. The present certificate is faulty in that it does not state the number of insertions made or the number successful, and another important omission is that it does not state the source of the lymph used. In the certificate, then, we ought to have the name and age of the child vaccinated, the name of the parent or guardian, if the parents are deceased, the place of birth, and the place and date of vaccination. The number of insertions made and the number successful are very important, as the small number of insertions, and consequent inefficient vaccination, is a charge frequently brought against private vaccination. It is not necessary to enter into a discussion as to the greater amount of protection afforded by multiple marks, but I simply direct attention to Marson's well-known figures, which have never been contradicted; in fact, all the later statistics only serve to confirm Marson's conclusions that for efficient protection four vaccine marks are necessary. In addition, however, to the power of efficient vaccination in preventing death we have also to consider its power of preventing attacks of small-pox. In addition to the statistics obtained by the Privy Council as far back as 1863, in which the protective power between the best vaccination and the worst vaccination is represented by the ratio eleven to one, we have the overwhelming evidence adduced by Dr. Barry of the Local Government Board in the report of his inquiry into the Sheffield epidemic of 1887–88.

In every certificate of successful vaccination the source of the lymph ought to be stated, whether vaccinated with calf lymph (in which case the name of the institution should be given) or with human lymph. As every certificate would be numbered this number could be inserted instead of a name, and every medical man would thus have a correct record of all the sources of lymph used by him. It would be the duty of the sanitary authority to keep a record of these, and thus in any case of suspected inoculation of any disease by means of vaccination the source of the lymph could be at once ascertained. This is, of course, done at the present time by public vaccinators, but very few medical men other than these keep a satisfactory record of the sources of their lymph.

The fee for the performance of vaccination ought to be paid by the sanitary authority at a fixed rate—at least, in towns and urban districts. In some rural districts the fee would require to be more elastic, although if the child be brought to the house of the vaccinator the same fixed fee would suffice, the amount of this fee ought, in my opinion, to be 3*s.* 6*d.* This is higher than the fee under the Notification Act, but in the latter the physician has no actual expenditure, whereas in vaccination the cost of lymph has to be considered. The parent or guardian ought distinctly to understand that the fee does not include any further attendance other than the act of vaccination and the inspection of it seven days thereafter. Further medical or surgical attendance ought to be paid for by the parent or guardian. The registrar at present sends the list of births as well as of deaths of infants to the vaccination officer and is paid a fee for so doing, so that the amendment that these be sent to the medical officer of health will cause no additional expense. No one knows what the Royal Commission on Vaccination will recommend, whether a continuation of the present system or an alteration of it in some slight way; but I am certain that a Bill on the lines I have mentioned would be more satisfactory as regards the efficacy of vaccination and that many objections to the operation would be thereby removed. The preliminary report issued by the Commission has been productive of no little harm; but it is to be hoped that better counsels will prevail, and that the report will emphasise the necessity of primary vaccination and the advisability if not the necessity of revaccination.

Church-row, S.W.

LITHOTRITY IN CASES OF STONE: SIMPLE AND COMPLICATED.

BY HERBERT MILTON, M.R.C.S. ENG.,
PRINCIPAL MEDICAL OFFICER, KASR-EL-AINI HOSPITAL, CAIRO.

(Concluded from page 1132.)

WITH regard to stones retained in a post-prostatic pouch my experience has been, in the few cases I have had, that urethral lithotrity was very easily performed and afforded successful results. In the more advanced cases referred to by Buckstone Browne I see no alternative but suprapubic cystotomy. The third category of complications are those arising from the incomplete development of infancy and childhood; in other words, from the smallness of the parts concerned. My personal experience of stone in children has been but small. In Egypt the very great majority of stones occur in subjects over ten years of age. The tables given with this paper do not demonstrate this point, but on reference to my records I find that out of the 200 cases given in Table I. 9 only were in children under ten, whereas Cheselden in 213 cases met with 105. In India, on the other hand, the proportion of children operated on is exceptionally large. The difference is due to the fact that stone in Egypt is principally caused by the alterations produced in the urinary system by the presence of Bilharzia

Digitized by Google

embryos, and that the Bilharzia parasite, while very common in adult males, is rare in women and children. The relative values of the various operations for children have been frequently discussed of late years in the medical journals. The Indian surgeons especially, following the example of Keegan and Freyer, have published many records and have very strongly advocated lithotrity for children of all ages. The results they have obtained have been remarkably good and equal—at least, the best results given by lithotomy. While, however, it must be accepted that the method is an excellent one as practised by experts, it is by no means certain that the general surgeon will find its adoption satisfactory. The conclusion I have come to is that when a surgeon is likely to have to treat many cases of stone in children it will be advisable for him to acquire the necessary ability that practice only can give, but that the surgeon called upon to treat such cases occasionally only will do better by keeping to the time-honoured operation of Cheselden. I have quite lately come across very useful information on this head in a paper by Gilbert Barling.[1] In it are given the results of 152 operations performed in various English hospitals between 1888 and 1892 on children under ten years of age. Of these, 43 were litholapaxy with 1 death, 46 were suprapubic lithotomies with 10 deaths, 48 were lateral lithotomies with 2 deaths, and 15 were median lithotomies with 1 death. These figures, giving the experience of many surgeons, represent, I think, the relative values of the different operations more fairly than the results obtained at the hands of a few specialists. It fully bears out what has been my opinion for long past that the results obtained by suprapubic operation in children are far from justifying the preference given to it in some quarters. Any considerable statistical evidence in its favour is still wanting, and this while statistics, to be counted by many hundreds, have been published by various operators showing a mortality of greatly under 5 per cent. for litholapaxy and perineal lithotomy. The fourth category of complications are those arising from old age and its degenerations, and it is in avoiding the dangers due to these complications that the most real difficulties of the surgeon lie. To-day, thanks to the great improvements in instruments and methods, and especially to the cleanliness so universally practised, the mortality rate of stone operations in children and adults is, at the hands of experts, almost *nil* or, as it might perhaps be expressed, it is reduced to the personal equation of the operator. When once the true percentage mortality of an operation or class of operations has been brought down to zero by any operator, as it has been done by more than one surgeon in India, in the case of stone, it is hardly justifiable to talk of the dangers inherent to the operation. I advisedly use the term true percentage mortality, being of the opinion that no percentage mortality can pretend to truth, and, therefore, should not be estimated until the number of cases cited can be counted by centuries. It is unjustifiable to calculate a percentage mortality from 99 cases as from one case, and I would express proportions deduced from such numbers as relative mortalities, taking for expression of the ratios the lowest possible whole numbers, thus 1 in 15 or 2 in 31. While, however, the percentage mortality of stone operations has been reduced almost to *nil* in adults and children, the results are quite otherwise when dealing with the aged. Old subjects support most operations fairly well, amputations are constantly successfully performed in extreme old age, and ovariotomy in very old women is almost as successful as amongst the young. Shock, if great care is taken to prevent loss of heat, is probably less marked in the old than in the young after operative interference. Old tissues, so long as elimination of effete products is fairly carried out, are probably not such suitable media for the development of most micro-organisms as the juicier tissues of the young. While, however, the susceptibility to attack is perhaps diminished, the power of expulsion of morbid products is generally greatly lowered. In youth and middle age the individual can assimilate most things, from the living organisms of various diseases to the toxines of lobster salad, with certain trust in its powers of elimination. In old age, while the resistance to attack by living organisms is perhaps greater, the powers of elimination are probably much diminished. The epithelial surfaces from their increased dryness and rigidity are perhaps more efficiently protective than when in a younger stage, but their power of excretion is proportionately enfeebled. It is probable that a preponderant share of the work of elimination is in old subjects carried on by the kidneys, and any morbid condition of the urinary apparatus has therefore a special importance. It is, moreover, in connexion with the urinary system that occur the local complications usually attending stone in old men. Chronic gouty or other changes in the kidney, atony of the bladder and cystitis, obstructive enlargement of the prostate, are often the accompaniments if not the original cause of the calculus. An old man the subject of such morbid conditions is already in a perilous condition, and the scales of life and death begin to balance. A slight addition to either means its preponderance, but the result is likely to be in the one case only temporary and in the other permanent. The first question that arises, therefore, is whether under any conditions any attempt should be made to remove the stone or not. It is difficult to adduce any evidence on this point. There are many statistics showing the mortalities of stone-operations in the aged, but I know of none showing what percentage of the cases met with had been operated on. The mortality attending any form of stone operation under the conditions mentioned must be high, and, on the other hand, the inconvenience produced by the stone is under such circumstances, as has been pointed out by Sir Henry Thompson, not unfrequently comparatively slight. Further, even in what are reckoned in statistical returns as successful cases the amount of relief after operation may be but slight. I think, however, the general opinion of the profession, and more especially of operators, is that relief should be attempted in practically all cases except those in which the condition of the patient is such as to contra-indicate all interference from fear of immediate death.

Having decided on operating, the question still lies as to which method should be pursued. Here I think there is but little doubt. Opinion is universally in favour of the crushing operation. In the paper above referred to 155 of the cases were in subjects aged over sixty years. Of these 118 were operated on by litholapaxy, with a mortality of 11, equal to about 9·2 per cent.; 26 by suprapubic lithotomy, with a mortality of 8, equal to very nearly 1 in 3; and 11 by perineal lithotomy, with a mortality of 2. Of course, in these as in other statistics the relative mortality of the operations may depend on other factors than their intrinsic merits, but the table is particularly valuable as showing the great preference accorded by surgeons in general to the crushing process in the treatment of stone in the aged. Still, even by this the most favourable method the mortality is very considerable. I am inclined to attribute the dangers of lithotrity in old men to two principal factors—firstly, the bruising of the urethra, neck of the bladder, and prostate by the frequent introduction of the instruments; and secondly, to the effect on a weak bladder of over-distension during the evacuating process. I think that anything which tends to diminish these two dangers would largely increase the advantages of lithotrity. I have sought to obviate the first factor by uniting the crusher and evacuator in a single instrument—the evacuating lithotrite referred to previously. I have alluded to the use of this instrument in simple stone cases, but it is in the treatment of the class of complications now under notice that its chief use is likely to be found. My experience of it is not yet sufficiently large to express any opinion of its value, but I think that it is worthy of trial. In order to obtain success in this as in other forms of stone operations in similar cases attention is necessary to the minutest details. The patient should be kept in bed for at least two days before operation; he should be kept on a regular nourishing diet suitable to his general condition. Milk should if possible be taken in quantity. The bowels should be gently opened on each of the two days by saline purge and enema. Any catheterisation that is necessary may be carried out, but I think that the more the urethra and bladder are left alone the better. I consider it to be a good routine practice to give from fifteen to twenty grains of diuretin twice daily during the two days. I think that this drug is very useful for washing and cleaning out the urinary and general system and is an excellent general stimulant. A good night's rest should if possible be obtained before the operation, which I think is best performed as early in the morning as is consistent with the comfort of the patient. During the operation the greatest care must be taken to avoid any loss of heat. The room must be well warmed and the patient, especially his extremities, well covered. Eggs, milk, and stimulants should be taken from one to two hours previously. The

question of anæsthesia is very important. Ether is, I think, in such cases often dangerous from its possible after-effects. Chloroform is preferable, although not free from danger; of other general anæsthetics I have no experience. I believe, however, that the use of an instrument capable of terminating the operation with a single introduction will obviate to a great extent the necessity for an anæsthetic. I have experimented with various drugs locally, but as yet without great success. Cocaine as an injection is, I think, too dangerous. Antipyrin in a 5 per cent. solution diminishes sensation considerably. Methylene blue in a 5 per cent. solution is even more effectual, but still does not sufficiently abolish sensibility. Up to the present I prefer to use chloroform narcosis, but I have found that a very small quantity of the drug is sufficient.

It is very important to use the largest instrument that can be introduced without putting any undue strain on the urethra. If small instruments be used the fragments extracted must of necessity be small and the operation in consequence prolonged. A fair idea of the capacity of the urethra may be gained from the size of its orifice. In most cases a No. 16 evacuating lithotrite may be used; in many, however, a No. 14 is the largest which can be easily introduced. The instrument must be well oiled and warmed and introduced with the minutest care. The point of the lithotrite having been introduced into the orifice should be allowed to find its own way down to the membranous portion of the urethra. The weight of the instrument is quite enough to effect this, and the left hand of the operator should only be used to keep it first horizontally and then perpendicularly in the middle line. During this passage the urethra must be put at its full stretch by pulling the penis vertically upwards with the right hand. There is a tendency for the lithotrite to be arrested on entering the membranous urethra, and it is here that the skill of the practised operator is required to ensure an uninterrupted, regular passage into the bladder. The moment before this arrest would take place the right hand of the surgeon leaves the extended penis and applies through the medium of the second and third fingers a pressure to the heel of the lithotrite. This, accompanied by the gradual depression of the handle between the legs of the patient, carries the jaws of the instrument smoothly through the membranous constriction, over the ridge of the prostate, and into the cavity of the bladder. It is during this moment, and at this time only, that any propelling force should be given by the left hand to the lithotrite.

It is my practice to wash out the bladder two or three times with boracic acid solution before proceeding to crush. I consider this process beneficial inasmuch as it cleans out the bladder before any considerable injury to the mucous membrane has taken place. For this washing out I always employ, as before stated, the hydrostatic douche at an elevation of about thirty inches. I generally leave from four to six ounces of solution in the bladder. The position of the stone is then carefully recognised and its seizure gently effected. The screw is applied slowly and deliberately. The stone is then crushed and the process repeated as often as possible until the débris is sufficient in quantity to become a hindrance. The evacuating syringe is then applied to the handle, the stop is withdrawn, and the male blade protruded. The bladder is then very carefully washed out, only a very small quantity of fluid being injected. This process of crushing and evacuation is continued until the stone is completely removed. This fact may be ascertained first by the absence of the passage of any débris and of the click of any large fragment against the jaws, and secondly by thoroughly exploring the bladder with the closed lithotrite. When using the instrument as a sound the blades should be screwed tightly home so as to prevent any rattling. The instrument is then withdrawn, leaving, as I have found best, from four to six ounces of boracic solution in the bladder. This operation, if carefully conducted, inflicts a minimum of damage on the urinary passages. It requires, however, great delicacy of manipulation and is apt to be more prolonged than lithotrity with the ordinary instruments. Two points should always be regarded in operating on old men: firstly, to practise the most extreme gentleness compatible with rapidity; secondly, to thoroughly explore the post-prostatic pouch and at the same time to fully utilise the advantages presented by it as a trap for fragments. The after-treatment of such cases is often as important as the operation itself. The bladder treatment should be entirely symptomatic. If it empties itself completely it should be allowed to do so; if not the urine should be drawn off with a sterile catheter every four or six hours. An alkaline condition of the urine should be treated by bladder douches, of which the best is, as I have found, a weak solution of permanganate of potash. A diminution of quantity of the urine should be obviated by demulcent drinks, such as barley water, and if necessary by diuretics, of which I think the best is diuretin. The patient's strength must be maintained by good feeding and by the exhibition of stimulants in such quantity as may be required. In case of febrile symptoms arising salicylate of soda, together with cognac, should be freely used. It is, of course, self-evident that the mortality of stone operations on the aged can never be reduced to the ratios obtained with youths and adults; still, a careful attention to details will considerably diminish the mortality dependent on senile changes. These changes, however, not only largely increase the dangers of the operation, but also in some cases from local alterations render its performance much more difficult. The alterations of the prostate, either in the form of general hypertrophy or the production of tumour, may be such as to cause in the first place great obstruction to the introduction of instruments into the bladder, or in the second more or less complete ensaculation of the calculus. The first difficulty, obstruction to the introduction of instruments, is usually to be overcome by careful manipulation. In some few cases the obstruction may be complete, and some form of cutting operation becomes necessary both for the relief of the retention of urine and for the removal of the stone. In the great majority, however, a fair-sized instrument may be introduced. It is in these cases that the evacuating lithotrite, if it can be introduced, is of chief benefit, as a single introduction of it allows of the completion of the operation. Here, as in most other cases of difficulty in introducing instruments into the bladder, a finger in the rectum is of the greatest assistance.

The retention of the calculus in a pouch behind the enlarged prostate is a matter of much greater importance. In the simpler examples of this condition, in which there exists only a dilatation of the normal trigonal pouch, operation is, as I have before remarked, rather facilitated than otherwise. Where, however, the pouch is more or less separated from the general bladder cavity by constriction of its upper margin, or where, as described by Buckston Browne, an overhanging tumour of the prostate entirely hides the calculus, lithotrity may become extremely difficult or even impossible. Under such circumstances relief can perhaps only be given by some cutting operation, but lithotrity should be, I think, attempted in most cases. It is sometimes possible to dislodge the stone by pressure exercised by a finger in the rectum. In such cases, however, a new point comes into consideration—the treatment of the complication itself. Many operations have lately been performed for prostatic tumour and with very encouraging results, such operations being nearly always performed through a suprapubic opening into the bladder. It becomes, therefore, a matter of consideration as to whether it would not be advisable, in all cases of stones co-existing with any considerable enlargement of the prostate, to remove both stone and tumour through the same opening. There are, however, several indications against the procedure. In the first place the results of lithotrity are, from the point of view of mortality, at any rate greatly superior to those of suprapubic lithotomy. Secondly, the diagnosis of a prostatic tumour likely to be benefited by operation is very difficult so long as a stone is present. Thirdly, after removal of the stone the prostate may give but little inconvenience. Fourthly, the wished-for diminution of the prostate may perhaps be more safely obtained by castration.

I would say, therefore, with regard to the treatment of stone when complicated by old age and its degenerations, that (1) lithotrity is attended in such cases with very much less mortality than any cutting operation and is, therefore, to be performed when possible; (2) that a further advantage may be gained in lithotrity by the use of an evacuating lithotrite; (3) that the minutest care is necessary in all such operations; (4) that where the stone is complicated by evident prostatic tumour the safer plan is to treat the stone first by lithotrity and then to determine on the nature of the interference necessary for the treatment of the prostate; (5) that some cases cannot be operated on by lithotrity and that some cutting operation, preferably suprapubic lithotomy, is necessary; and (6) that lithotrity in difficult cases may be greatly assisted by the manipulations of a finger in the rectum.

The next varieties of complications that I have to refer to are those arising from the various pathological conditions of the urinary system. The conditions usually considered of importance are organic disease of the kidneys, cystitis in all its varieties, new growths of the bladder, urethral obstruction, prostatic hypertrophy and tumour, and tendency to hæmorrhage. Organic disease of the kidneys, as evidenced by the quantity of urine passed and by the presence of urinary casts, undoubtedly furnishes a very important item in prognosticating the result of any operation. Still, there is no condition of the kidney which could be taken as a contra-indication to operation. When, however, the question arises as to which operation, the crushing or the cutting, is likely to yield the better result it becomes very difficult to adduce trustworthy evidence. Lithotrity has, however, proved itself to be the best operation for cases of stone in general; and as pre-existing kidney disease is generally held responsible for the fatal results occurring amongst patients of middle age, this operation, yielding as it does the smallest general mortality, is probably the best suited to meet this special complication. The existence of severe cystitis is also an important element in cases of stone. Here, however, we stand on much surer ground in deciding between the merits of the two operations. The cystitis which is so frequent a companion of stone generally disappears after its removal. My experience has been very clear on this point, that the cure of the cystitis after lithotrity has been as certain as after lithotomy. As to the rapidity of the cure evidence is lacking, as until the urine passes per urethram instead of by the perineal or other wound it is difficult to determine the condition of the bladder. In lithotrity cases, however, the cystitis is usually cured long before the period at which a lithotomy wound is closed. I consider, therefore, that the presence of cystitis, however severe, is no contra-indication to lithotrity. There are, however, two points which must not be lost sight of. The one is that fever is by no means uncommon after lithotrity in severe cases. This fever is, I believe, as a rule due to septic absorption from the bladder and urethra and may call for active treatment. The rise of temperature may be accompanied by diminution in the quantity of urine secreted, a condition which cannot fail to give rise to anxiety.

The treatment of these complications after lithotrity has in Egyptian subjects been so successful as to become practically a routine. If there is fever salicylate of soda is given in doses of 1 gramme every two hours for four doses and then every four hours as long as necessary. If there is diminution of urine diuretin is given in similar doses every four hours. When there is persistent cystitis the patient receives 0 30 grammes of methylene blue daily. This latter drug I have found most useful for cystitis, and it is particularly beneficial from its anodyne action. In very severe cystitis, especially if accompanied by atony or by a cystic condition of the bladder, whether after lithotrity or otherwise, a perineal incision and drainage of the bladder is the most certain cure. Still, although in a few very rare instances a lithotrity may require to be followed by a perineal incision. it is better in my opinion to resort to the cystotomy as a secondary than as a primary operation. The presence of a tumour in the bladder greatly complicates any stone operation, so much so that one would be justified rather in looking upon the tumour as the important disease and the stone as the complication. In most cases, however, the tumour is unsuspected until disclosed by the operative procedures; in many cases even the suspicion does not arise until after removal of the stone symptoms persist the significance of which was previously masked by its presence. In a few cases the presence of a tumour may be suspected from the results of sounding or other examinations. As to symptoms, I would call attention to two only: the first is the presence of an unusually large quantity of blood in the urine, which frequently occurs in these cases and should raise suspicion, and the second is the passage by the urethra of a fragment, microscopical or other, of a tumour, which seldom occurs, but which assures diagnosis. The age of the patient has a certain importance. In my experience the simple papillomatous tumour of the bladder exists much more frequently in youth than in adult life. Age, of course, predisposes to malignant tumours. The signs yielded by a benign bladder tumour on examination are, as a rule, not very evident, and their detection is, of course, rendered much more difficult by the existence of a stone. A small mobile papilloma has been detected by a sound, but in my own experience, at all events, it has been detected more often than it existed. A villous tumour is, I believe, not capable of detection by any manipulation except in very rare cases. The examination should always be bimanual—that is to say, between the sound in the bladder and a finger in the rectum, between the same sound and a hand over the pubis, and between the finger in the rectum and the hand over the pubis. A large carcinomatous infiltration of the bladder may be generally very easily recognised; smaller tumours, however, although malignant, frequently escape detection. The cystoscope may be used in doubtful cases should the condition of the urine admit of it, and in practised hands may yield very useful information. During the operation for stone the tumour, if of any size, may usually be detected. Any form of cystotomy, laying the bladder open as it does to digital exploration, renders its detection very easy. This exploration can be carried out most easily through a suprapubic incision, but can in most cases be as effectually performed through a lateral perineal wound. During lithotrity also a tumour is, I think, generally detected unless very small. It may show itself by extra difficulty in the manipulation of the lithotrite. In most cases fragments of tumour are brought away either in the jaws of the instrument or through the evacuator. A bladder tumour having been detected in conjunction with a stone, what is the best line of treatment to pursue? The course to be pursued depends on the age of the patient, the probable nature and size of the tumour, and on the size of the stone. If the patient be young, the tumour probably benign, and the stone not very big, the removal of the stone should be considered as secondary to the removal of the tumour, and therefore a suprapubic cystotomy be performed. In a similar case, should the stone, however, be large, I think that the safer proceeding would be to remove the stone first by lithotrity and to perform a suprapubic cystotomy later for the removal of the tumour. I am led to this conclusion by the fact that whereas the mortality after suprapubic cystotomy for tumour is small the same operation for large stones is still attended with great risk. On the other hand, should the tumour have bled freely, especially after examination with a sound, the suprapubic operation should, perhaps, have the preference, as lithotrity in such a case has been followed by very severe or even fatal hæmorrhage. Should the patient be old, should the tumour be probably malignant, and should the question of extirpation of the tumour be not entertained I should recommend the removal of the stone by lithotrity. I have performed this operation in three cases of evident carcinoma of the bladder—in all with success. The presence of the tumour, while rendering the operation more difficult and necessitating great care, produced no untoward after-symptoms. I would say, therefore, that in a case of stone and tumour diagnosed as existing in the same bladder the choice of operation lies between suprapubic cystotomy and lithotrity, and that the first is in general indicated whenever the tumour is to be removed and the second whenever this is impossible; that in the case of a very big stone it may be advisable to do the two operations at different times; and, finally, that the presence of a tumour, unless it be very prone to hæmorrhage, is not an indication against the performance of lithotrity. Urethral obstruction may, of course, be an absolute bar to lithotrity. Generally, however, the stricture is capable of cure, and then the question may arise as to the superiority of the various methods for the removal of the stone. If the stone be small I should consider the stricture as the more important, and should treat it first by dilatation or (in bad cases) by perineal incision. In the first case I should remove the stone by a subsequent lithotrity and in the second I should remove it at once through the perineal wound. On the other hand, should the stone be large (say, over thirty grammes) I should consider it to be the more important disease—firstly, on account of its size, and secondly, because the introduction of large crushing instruments is often difficult, even after complete dilatation of a stricture. In such cases I should recommend a perineal incision, followed by crushing of the stone and its removal through the wound. Where the stricture is such as not to admit the smallest staff it may be advisable to dilate the urethra first and then to perform perineal lithotrity. Briefly, then, I would say, when the stricture is incurable and no staff can be introduced suprapubic cystotomy becomes almost a necessity. When the stone is large and a staff will pass perineal lithotrity is preferable; when the stone is small the stricture should be treated by dilatation and urethral lithotrity subsequently performed. Prostatic hypertrophy

Digitized by Google

and tumour I have already referred to in treating of senile degenerations. The tendency to hæmorrhage I have referred to under the observations on bladder tumours. I have never met with anything approaching to severe bleeding in any crushing operation. Should it occur the best method of treatment is to wash out the bladder with a large lithotrity evacuator and syringe. Should it recur, and should the various hæmostatic local applications in the form of bladder douches be ineffectual, I would drain the bladder by a perineal incision and wash it out with an iced creoline solution every two hours. The last category of complications are those arising from the general health of the patient. On this point there is but little to be said. I know of no condition except impending death from other causes than the presence of a stone which contraindicates operation. Heart disease is, unless extremely advanced, rendered innocuous by anæsthesia. Affections of other organs, although requiring the most careful attention before, during, and after operation, do not exclude its performance. Hæmophilia, an extremely rare complication of stone, renders operative interference more than usually imperative, and in such a condition lithotrity is clearly indicated. The general condition of the patient, therefore, may be said to present no indication against the operative treatment of stone, neither does it, with the exception of hæmophilia, specially indicate any one operation. The operation which gives in general the smallest mortality is, however, most necessary when the chances of mortality are increased, and lithrotrity therefore in such cases imposes itself.

In recapitulation I would say:—(1) That litholapaxy—i.e., lithotrity at a single sitting—is certainly the operation of election in all simple cases of stone in the urinary bladder; (2) that the difficulties of lithotrity increase with the size of the stone, but that no stone is too large or too hard to be crushed, and that the results obtained by lithotrity in dealing with stones over two ounces in weight are greatly superior to those ever obtained by any other method; (3) that in cases of large and hard stones in which, from the lack of operative skill and experience, urethral lithotrity is abandoned the best results will be given by a crushing operation performed through a perineal wound; (4) that difficulties in grasping a stone may be obviated by the use of suitable instruments and by cautious dilatation of the bladder; (5) that a considerable proportion of stones encysted in various ways may be removed successfully by lithotrity, and that only when this has been attempted and has failed should cystotomy, preferably suprapubic, be reverted to; (6) that lithotrity is the operation of election in the presence of nearly all morbid changes of the genito-urinary apparatus and should always be attempted, the necessary treatment being afforded to the complication either before or after its performance as required; (7) that in children its results are particularly favourable when carried out by experts, but that for the present lateral lithotomy is the safer operation in many hands; (8) that in the presence of senile degenerations and of morbid alterations of the general system lithotrity is by far the best operation and should be carried out whenever possible; and (9) that the completion of the operation by means of a single instrument—the evacuating lithotrite—may be advantageous, especially when dealing with old subjects.

Cairo, Egypt.

STREPTOCOCCUS PYOGENES AND ANTI-STREPTOCOCCIC SERUM.

BY WILLIAM BULLOCH, M.D. ABERD.,
BACTERIOLOGIST IN THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

THE results here detailed refer for the most part to attempts made by Dr. Armand Ruffer and myself to render large animals immune against streptococcus pyogenes for the purpose of obtaining a specific therapeutic serum. The experiments were begun by Dr. Ruffer in the spring of 1895 and in autumn the partially immunised animals were taken over by me for the completion of the process of immunisation. Two horses have been immunised against streptococcus pyogenes alone; two others were first rendered immune against diphtheria toxine and then against streptococcus pyogenes, in the hope that the serum would be of value in antagonising the action of the very common polymicrobic infection, the Klebs-Löffler bacillus and streptococcus pyogenes. At first considerable difficulty was experienced in keeping the cultures of streptococcus alive through several generations. Further, the method of passage, although early resorted to, was only partially successful on account of the rapid loss of virulence of the micro-organism in ordinary liquid nutrient media. In July, 1895, Marmorek published an article on the streptococcus and described certain media in which the virulence obtained by passage could be maintained for a greater or less length of time. Since this publication we have used these media exclusively and have in the main been able to confirm Marmorek's observations. Human blood serum (two parts) and peptonised bouillon (one part) undoubtedly form the best medium; on account of the difficulty of obtaining human blood in quantity we have also used ascitic fluid bouillon. It must, however, be remembered that ascitic fluid from different patients varies a good deal. Some samples conserve the virulence of the micro-organism well, whilst others are distinctly inferior in this respect. A mixture of two parts donkey's serum and one part of bouillon is also good, although inferior to ascitic fluid. The fact that the passage of the streptococcus pyogenes through a series of rabbits increases the virulence of the microbe is an old one. The method of obtaining the greatest degree of virulence in the shortest possible time is to commence the series of passages by intravenous inoculation with intermediate cultivation from the cardiac blood. After one or two passages the series should be continued by subcutaneous inoculations in the abdomen, with subsequent cultivation from the liver. The streptococcus used in these experiments was obtained by Dr. W. R. Smith from a case of erysipelas in University College Hospital. Its pathogenic action at first was weak. Two cubic centimetres of bouillon culture killed the first rabbit in three days. A small quantity of the culture which escaped into the subcutaneous tissue of the ear produced a typical "ear erysipelas." Cultures were made from the cardiac blood in ascitic fluid bouillon, and after a sojourn of eighteen hours in the incubator a second passage was made. After the third passage the cultures, in gradually diminishing doses, were inoculated subcutaneously, and cultivations for the continuance of the series were made in serum bouillon. By the end of three months a very high degree of virulence was obtained, the animal succumbing in from twenty-four to thirty-six hours with general streptomycosis. At the point of inoculation a slight exudate is observed. The viscera are all congested and pleural and peritoneal exudates are frequent. Cover-glass preparations show that the organs are teeming with cocci. In animals dying within thirty hours we have found these almost exclusively in the form of diplococci. Sometimes the diplococci looked as if surrounded by a capsule. Cultivations made from the liver showed that up to three or four hours after inoculation the diplococcic form prevailed. By the sixth or eighth hour the cocci were in short chains of from four to eight members. In from eighteen to twenty-four hours the chains were often so long as to extend unbroken across two or three fields of the microscope—a veritable streptococcus longus. The inoculation of these very long chains caused death in rabbits more slowly than the diplococci, but post mortem diplococci were again almost exclusively found if the examination was made immediately after death. Where the necropsy was performed several hours after death (animals dying during the night) short chains were found in the exudates into the serous cavities and even in the blood. From the observations we have made we believe that the distinction of streptococci into varieties depending on the length of the chains (Behring, von Lingelsheim, Kurth, Knorr, and others) is not of much value.

IMMUNISATION OF HORSES.

1. Black cob mare, weight 9 cwts. Between May 11th and July 22nd, 1895, 415·5 c.c. of bouillon cultures from successive passages in rabbits were injected hypodermically in doses varying from 0·5 c.c. to 100 c.c. Each injection was accompanied by a large swelling at the point of inoculation and extending between the forearms along the front of the abdomen. Severe constitutional symptoms, fever, rapid breathing, &c., also showed themselves. During the last six months 498 c.c. of virulent ascitic fluid bouillon cultures have been inoculated, spread over twelve injections. The local reactions have been enormous and the temperature after each inoculation has been high (up to 105° F.). As a

Digitized by Google

rule the animal has shown great sensibility and sometimes abscess formation has resulted, the pus containing pure cultures of streptococci of very active pathogenic qualities. In the case of the inoculation of large quantities it has been found advisable to limit the amount injected at one point to 25 c.c. In this way the discomfort to the animal is materially lessened.

2. Heavy cart gelding, weight 15 cwts. Between April 6th and July 20th, 1895, 303·5 c.c. of bouillon cultures were inoculated in quantities varying from 0·25 to 60 c.c. As this animal was more refractory than Horse 1 we have been able in the last six months to inoculate 640 c.c. highly virulent cultures grown in Marmorek's media. The febrile disturbance following the injections has been marked.

3. Heavy cart gelding, weight 16 cwts. From Nov. 17th, 1894, to April, 1895, this animal received 3810 c.c. of diphtheria toxine. A sample of blood taken on April 17th was found to have very high protective properties when tested against diphtheria toxine. The immunisation against diphtheria was now stopped, and between April 22nd and July 20th 371·5 c.c. of bouillon cultures of streptococcus were inoculated, with an occasional dose of 300 c.c. of normal diphtheria toxine. From Sept. 20th, 1895, to Jan. 20th, 1896, 444 c.c. of ascitic fluid bouillon cultures were injected in doses varying from 3 c.c. to 110 c.c. At first this animal exhibited slight reactions in comparison with Horses 1 and 2. Later, however, the injection of highly virulent cultures caused severe local and general reaction. The discontinuance of the injections of diphtheria toxine was found to have led to a marked loss of antitoxicity of the serum, although the animal had remained highly immune. Since March 4th 300 c.c. of diphtheria toxine have been inoculated.

4. Heavy cart gelding, weight 15 cwts. As in the case of Horse 3, this animal was first immunised against diphtheria toxine. Between April 22nd and July 20th, 1895, 366·5 c.c. of bouillon cultures of streptococcus were inoculated. From Sept. 20th, 1895, to Jan. 22nd, 1896, 578 c.c. of ascitic fluid bouillon cultures were injected. From Feb. 3rd to March 5th 1360 c.c. of N_2 diphtheria toxine were inoculated. Like Horse 3, this animal lost a good deal of the antitoxicity of the serum against diphtheria toxine.

General remarks.—Horses 1 and 2, which had been immunised against the streptococcus alone, were throughout more sensitive than Horses 3 and 4, which were first immunised against diphtheria toxine. During the period of reaction all the horses have suffered in general health. They have also all suffered from patches of alopecia which, in the opinion of an eminent dermatologist who examined the hair and the skin, was comparable to the alopecia following severe febrile disturbance in the human subject. (Compare the severe alopecia frequently seen after facial erysipelas.) A temperature chart showed a characteristic rise of temperature after the inoculation of 50 c.c. of serum bouillon culture of streptococcus pyogenes. The temperature rose steadily from 38° C.—the normal temperature of the horse—at 4 P.M. to a fraction below 41° C. (105·4° F.) at 10 P.M. At 1 P.M. the decline began, and by the evening of the following day a point a fraction above the normal was reached. At various periods samples of blood were drawn to estimate the preventive and curative power of the serum, as also to determine the length of time during which the serum remains toxic after inoculation. Marmorek found that from 0·5 c.c. to 1 c.c. of serum taken fifteen days after inoculation killed rabbits weighing 1500 grammes in from five to ten days. In the following experiment Horse 4 was inoculated at 12 midnight, Dec. 4th, 1895:—

Rabbit 1, serum taken at 6 A.M., Dec. 4th = 5 c.c. subcutaneously injected; died in five days.
Rabbit 2, serum taken at 5 P.M., Dec. 4th = 5 c.c. subcutaneously injected; ill but recovered.
Rabbit 3, serum taken at 12 noon, Dec. 5th = 5 c.c. subcutaneously injected; alive and well on March 4th, 1896.
Rabbit 4, serum taken at 12 noon, Dec. 6th = 5 c.c. subcutaneously injected; alive and well on March 4th, 1896.
Rabbit 5, serum taken at 12 noon, Dec. 7th = 5 c.c. subcutaneously injected; alive and well on March 4th, 1896.
Rabbit 6, serum taken at 12 noon, Dec. 10th = 5 c.c. subcutaneously injected; alive and well on March 4th, 1896.

According to this experiment the blood serum does not remain toxic for so long a period as that found by Marmorek.

The curative effect of the serum in experimental streptomycoses is shown below. The serum of Horse 2 was first used. In this experiment the control rabbit received a minimal lethal dose and died in twenty-four hours.

Rabbit 1 received ten lethal doses intravenously + 0·05 c.c. serum subcutaneously.
Rabbit 2 received ten lethal doses intravenously + 0·02 c.c. serum subcutaneously.
Rabbit 3 received ten lethal doses intravenously + 0·01 c.c. serum subcutaneously.

The results were that Rabbit 1 was alive and well two months afterwards; Rabbit 2 died in twelve days from metastatic lesions; and Rabbit 3 died in six days from the same cause.

The serum of Horse 4 was next employed. The control rabbit died in thirty-six hours after a minimal lethal dose.

Rabbit 1 received four lethal doses intravenously + 0·01 c.c. serum subcutaneously.
Rabbit 2 received four lethal doses intravenously + 0·008 c.c. serum subcutaneously.
Rabbit 3 received four lethal doses intravenously + 0·006 c.c. serum subcutaneously.

The results were that Rabbit 1 showed no symptoms and is alive at the end of two months; Rabbit 2 died in five days with metastatic lesions; and Rabbit 3 died in seventy-two hours with streptococci throughout the entire body.

The preventive power of the serum of Horse 1 is shown in the following experiment, in which the control rabbit (which weighed 1350 grammes) after eight times the lethal dose died in twenty-four hours.

In Rabbit 1 (weight 1550 grammes) = 0·2 c.c. serum was subcutaneously injected on Feb. 19th at 10 A.M. + 10 lethal doses on Feb. 20th at 1 P.M., with the result that it was alive and well on March 16th.
In Rabbit 2 (weight 1600 grammes) = 0·05 c.c. serum was subcutaneously injected on Feb. 19th at 10 A.M. + 10 lethal doses of culture of streptococcus on Feb. 20th at 1 P.M. On March 5th it was alive and well, but died on March 7th with acute psorospermosis. There was no evidence of streptococci post mortem.
In Rabbit 3 (weight 1800 grammes) = 0·01 c.c. serum was subcutaneously injected on Feb. 19th at 10 A.M. + 10 lethal doses of culture of streptococcus on Feb. 20th at 1 P.M. It died on March 1st with streptococcic pleurisy and peritonitis and metastases.

In comparison with anti-diphtheritic or anti-tetanic serum the curative effect of anti-streptococcic serum appears to be slight; still, it must be remembered that the successive passage through rabbits renders the streptococcus so virulent that it is mortal to rabbits in very minute doses. Further, the horse must remain under treatment at least a year before the serum reaches its maximum anti-streptococcic strength.

With regard to the dose of serum, for severe cases of puerperal strepto-mycosis 10 c.c. should be injected on each side of the abdomen as an initial dose, followed by another of from 10 to 20 c.c. if the temperature has not fallen, but much larger doses can be given with safety. In streptococcic angina from 10 to 20 c.c. may be injected according to age. Experimentally we have found that 10 c.c. injected into rabbits cause no bad symptom whatever, and in the human cases already treated no unfavourable results have yet been recorded which could be referred to the serum itself. The true value of anti-streptococcic serum will remain doubtful for some time on account of the difficulty of diagnosing streptomycoses bacteriologically, for it must be remembered that the serum is specific against the streptococcus only and attempts to cure staphylo-mycoses by it will be failures (as in several reported cases where the diagnosis of staphylococcus was made only after death). In conclusion, I take this opportunity of thanking Dr. Armand Ruffer, lately Director of the British Institute of Preventive Medicine, for much help and advice throughout the whole work. To Mr. W. Robertson, Veterinary Surgeon to the Institute, I am also indebted for the notes and temperatures and clinical histories of the horses which have been immunised.

Sudbury, Harrow.

THE DIETARIES OF BENGAL GAOLS.

BY SURGEON-CAPTAIN W. J. BUCHANAN, B.A., M.B. DUB., DIPL. STATE MED.,
SUPERINTENDENT OF THE CENTRAL GAOL, BHAGALPUR, INDIA.

IT has been lately stated in an English medical paper and in the public press in India that the scales laid down for the diets of native prisoners in the gaols of India, and of Bengal in particular, are deficient, one critic says, in albuminates, fats, and salts. The following note will, I think, show that there is no foundation for such statements, and that the diets supplied for native prisoners in the gaols of Bengal are sufficient and indeed liberal. It is not here necessary to occupy space in quoting the analyses upon which the following calculations have been based. They

Digitized by Google

have been taken from the standard authorities, Parkes, Wynter Blyth, Wanklyn, Bell, and König in Europe, and Dr. T. Lewis and Dr. Lyon in India. The following is the scale of diet ordered by the Bengal gaol code for prisoners confined in these gaols. I may say that we have in Bengal no progressive scale of diets, the only distinction made is between the diets for labouring and *non*-labouring prisoners.

Bengal scale (for labouring prisoners).—Morning meal (1 chitak = 2·05 oz.): rice, 4·10 oz.; or flour, 3·4 oz.; or suttoo (grain pulse), 3·7 oz.; with molasses, 1 oz., or salt, ½ oz. The other two daily meals are given at 11 A.M. and 5.30 P.M. They are as follows: rice, 22·55 oz.; pulse, 6·15 oz.; vegetables, 6·15 oz.; salt, 0·76 oz.; condiments, 0·25 oz.; oil, 0·51 oz.; and tamarind, &c., 0·25 oz.; half at each meal.

This is the ordinary diet for natives of Bengal; the morning meal is varied as above. Still further variety is given by a change in the kind of vegetables issued and in the kind of pulse (*dâl*), five different sorts of which, of practically equal nutritive value, are in common use. The nutritive value of this diet is given in Table I. No. 1 gives its value if rice is given for the "morning" meal, and No. 2 if "grain suttoo" is given instead of the rice at this meal. The values of these diet scales are given both in terms of the proximate aliments and in terms of nitrogen and carbon. As Professor Parkes has said, "The phenomena of nutrition are chiefly owing to the various chemical interchanges between nitrogen and carbon"; therefore, the amounts of these two elements in a diet furnish us with a convenient and simple index of the approximate nutritive value of any combination of food materials.

TABLE I.—*Bengal Scale Diet.*

—	Albuminoids (N×6·3)	Fats.	Carbohydrates.	Salts.	Nitrogen.	Carbon.
	oz.	oz.	oz.	oz.	gr.	gr.
No. 1.—Rice, pulse, &c. (rice for morning meal)	3·55	0·866	26·5	1·11	250	5777
No. 2.—Rice, pulse, &c. (grain for morning meal)	4·01	0·888	24·90	1·17	284	5781

TABLE II.—*Behar Scale Diet.*

—	Albuminoids (N×6·3)	Fats.	Carbohydrates.	Salts.	Nitrogen.	Carbon.
	oz.	oz.	oz.	oz.	gr.	gr.
No. 1.—Wheat, rice, &c. (rice for morning meal)	4·12	0·93	25·1	1·13	292	5957
No. 2.—Ditto (grain for morning meal)	4·58	0·96	23·5	1·18	327	5781
No. 3.—Wheat, maize, rice, &c. (rice for morning meal) ...	4·07	1·27	25·6	1·25	288	6130
No. 4.—Wheat, maize, rice, &c. (grain for morning meal) ...	4·53	1·29	24·0	1·32	322	5954
No. 5.—Maize, rice, &c. (rice for morning meal)	4·03	1·60	26·1	1·37	282	6306
No. 6.—Maize, rice, &c. (grain for morning meal)	4·49	1·63	24·5	1·30	318	6130

Table II. gives the nutritive value of the diets in use in that part of the province of Bengal called Behar. It is given to all prisoners in Behar gaols or to Behari or up-country men in all Bengal gaols. The difference between it and the "Bengal scale" diet consists in the substitution at one of the daily meals of wheat, maize, millet, or a mixture of these for part of the rice. This is in agreement with the dietetic habits of the people of this part of India. The staple food of the inhabitants of Bengal proper is rice; that of Behar is wheat or other cereal, as maize, millet, &c. The above tables, therefore, give the values of the diets in actual daily use of prisoners confined in gaols under the Government of Bengal. A glance at the standard diets given in all the text-books—e.g., Moleschott's or Pettenkofer's—will show how well these gaol diets compare with the standard ones of the above eminent physiologists. The relative value of the gaol diets, however, becomes still more great when it is considered that the standard diets above referred to are intended for Europeans with an average body weight of 150 lb. (69·5 kilos), whereas the average weight of Indian prisoners was taken by Dr. T. Lewis, F.R.S., as 110 lb. That this is a fair and even liberal estimate of the average weight of Indian prisoners is clear from the following considerations. Dr. Lewis put the average weight of Bengal prisoners at 105 lb. Dr. Lyon found 105 lb. to be an average weight of certain prisoners in a Bombay gaol, and I have found as the result of over 15,000 weightments collected in the Central Gaol, Bhagalpur, that 109 lb. was the average of this large number. Therefore, we may accept 110 lb., with Dr. Lewis, as a liberal average weight for the prisoners whose dietaries are here being considered. At the same time, Dr. Lewis, taking from 140 lb. to 160 lb. as the average weight of Englishmen of all classes, took 145 lb. to represent the average weight of convicts in English prisons. When, therefore, the above gaol diet scales are compared with European standards this important difference in body weight must be remembered. Remembering this fact, let us take the highest scale of diet in use for long-term prisoners in English convict prisons and compare and adapt this to the proportionate requirements of an Indian prisoner. Dr. Burney Yeo, in his valuable manual on "Food in Health and Disease," quotes from the Eleventh Report of the English Prison Commissioners the following diet for long-term, hard-labour prisoners:—

TABLE III.

—	Albuminoids (N×6·3)	Fat.	Carbohydrates.	Salts.	Nitrogen	Carbon.
	oz.	oz.	oz.	oz.	gr.	gr.
English convict prison diet; Class IV.; men with long terms; hard labouring ...	4·09	1·30	20·17	1·55	262	5699

Comparing this with the gaol diets given above it is seen that there is very little difference. Yet this diet scale for men of 145 lb. average weight has been associated with a very high degree of health among English prisoners. Let us adapt this diet by a simple rule of three to the proportionate requirements of Indian prisoners of 110 lb. average weight. It works out as follows:—

TABLE IV.

—	Albuminoids (N×6·3)	Fats.	Carbohydrates.	Salts.	Nitrogen.	Carbon.
	oz.	oz.	oz.	oz.	gr.	gr.
Class IV., English convict diet, adapted to Indian prisoner of 110 lb. weight, average	3·10	0·98	15·3	1·1	199	4·243

Compare, then, this adapted diet with the Bengal and Behar scale values given in Tables I. and II. above, and it will be seen that our gaol diets are superior in every particular. The carbohydrates and albuminoids are especially superior in the Indian gaol diets. If we consider the amount of nitrogen given in the above Table III., which is considered to be sufficient for men of 145 lb. it will be seen that the amount of nitrogen contained in the ordinary Bengal diet (Table I.) should suffice for men of from 133 lb. to 157 lb. weight, and the ordinary Behar scale diets (Table II.) for men of from 157 lb. to 180 lb., whereas we have seen the average weight of these prisoners is only 110 lb., and men of over 150 lb. are very seldom seen in Bengal gaols.

The preceding remarks and figures have shown therefore that, judged by European and scientific standards, after due adjustment to meet the altered conditions of physique, climate, and habits of life, the ordinary diets of Bengal gaols contain in sufficient quantity all the elements of food necessary to maintain vigorous existence on ordinary work. In addition, however, the medical officers of gaols (who are in the great majority of cases also the superintendents or governors) have ample power given to them to make many variations suitable to the season and the general health of the prisoners. These variations are not made so much with the object of increasing the quantities of food supplied as to relieve monotony and give variety to the diets. In addition to

Digitized by Google

varying the kind of pulse and vegetables issued the medical officer can vary the antiscorbutic pickles used (as lemon, mango, or tamarind), or he can change the morning meal as above described or issue extra antiscorbutic vegetables, as onions and potatoes, or give extra salt and oil. Also, when there is a [general falling off in health or at unhealthy seasons the medical officer is enjoined to issue meat, fish, or milk in lieu of part of the pulse in the above diets, and Rule 106 of the gaol code directs that the fish or milk be issued in lieu of part of the pulse in quantities of equal nutritive value. I have calculated the nutritive value of meat, fish, milk, and pulse to be as follows: one part pulse equals two parts meat, two parts fish, or four parts milk. The principle of giving the nutritive equivalents in all cases of variations in diets is fully worked out in the revised gaol code which is now being published. Using, then, the above nutritive equivalents the value of a diet containing meat, for example, is seen in the following table.

TABLE V.—*Permissive Diets.*

—	Albuminoids(N×6·3)	Fats.	Carbohydrates.	Salts.	Nitrogen.	Carbon.
Bengal scale:	oz.	oz.	oz.	oz.	gr.	gr.
Rice, pulse, &c. (meat in lieu of part pulse)	3·65	1·17	25·3	1·13	258	5673
Rice, pulse, &c. (meat in lieu of part pulse; grain for morning meal)	3·71	1·19	23·7	1·18	290	5677
Behar scale:						
Rice, pulse, and wheat (meat in lieu of part pulse)	4·22	1·24	23·9	1·25	299	5853
Rice, pulse, and wheat (meat in lieu of part pulse; grain for morning meal)	4·68	1·26	22·37	1·20	333	5677

The above table might be indefinitely increased if we considered the values of diets containing maize, millet, or if we gave those substituting fish, milk, &c., for part of the pulse, but the values are practically the same. It will, therefore, I think, be agreed that the strictures lately levelled at the dietaries of the gaols in the province of Bengal are without foundation in fact, that the ordinary diets are liberal for ordinary conditions of health, and that ample power has been given to medical officers to vary to a very considerable extent the diets to meet the requirements of sickness or a general lowering of the prisoner's health. It has been laid down as an axiom of English prison management that the diet of prisoners should be "sufficient, and not more than sufficient," to maintain them in health and strength. I think it will be agreed that the Bengal gaol diets are even more liberal than this. These gaol diet scales have been in force since the year 1881; it cannot, therefore, be considered that they are answerable for the comparative unhealthiness of some gaols in the province. The gaol death-rate for the whole province for many years past has shown a decline upon the whole continuous and satisfactory. In 1895 it will be found to have reached the lowest on record (about 25 per mille). This very satisfactory result is not claimed as a result of the diets, but is due to the great care and attention bestowed upon sanitation, clothing, housing, and the provision of a good water-supply for the prisoners. If it is objected that though the scales above discussed are admittedly ample and even liberal, yet the prisoners do not get the full quantities ordered for them, the reply may be made that first it is the primary interest of the medical superintendent to have as low a sick- and death-rate as possible, and secondly, year by year it is proved that the vast majority of prisoners either remain stationary or gain in weight—e.g., take Statement B of the Annual Administration Reports on Bengal Gaols. Here it is shown from year to year that no less than 80 per cent. of the prisoners discharged have either not lost or have gained in weight during their stay in gaol, leaving only 20 per cent. who have lost, the latter number being easily accounted for by sickness. In conclusion, I think it has been shown that the gaol diets in ordinary use are sufficient and ample and that due discretion has been allowed to medical officers to alter or vary the diets according as they may consider necessary. The foregoing report has been submitted to, and has the approval of, the Government of Bengal.

Central Gaol, Bhagalpur.

ST. GEORGE'S HOSPITAL.

TWO CASES OF ACUTE PEMPHIGUS TREATED BY ARSENIC, WITH AN ACCOUNT OF SOME BACTERIOLOGICAL EXPERIMENTS.

(Under the care of Dr. THOMAS WHIPHAM.)

THE following two cases of acute pemphigus have lately been under observation in St. George's Hospital. Both were of unusual severity; one patient recovered and the other died. Both were treated by increasing doses of arsenic, and in both the remarkable effects of the drug in this particular disease were strikingly illustrated. This contribution to the literature of pemphigus is also a valuable one in many other respects. The account of the bacteriological examination of the cases is very complete and adds considerably to our knowledge. We refer our readers to the remarks appended to the case for much interesting information.

CASE 1.—A married woman thirty-eight years of age was admitted into St. George's Hospital on Nov. 21st, 1895. Her family history was good. She had been married ten years, but had never been pregnant. She was liable to sore-throat occasionally, but the attacks were of short duration and not severe. In the previous year she had "a touch of rheumatism," but there was no history or evidence of syphilis. A week before she came under observation a spot appeared on one of her fingers, which she "broke" and afterwards washed some clothes, using ordinary washing soda in the process. Immediately on this followed a copious eruption of "spots" on the face, then on the body, hands, arms, and legs. Her husband was in work and she suffered no privations, her diet consisting daily of bread, butter, meat, and vegetables. The sanitary arrangements of the house in which she lived were, so far as she knew, good. Up to the time when the first spot appeared on her finger she had been in good health. The eruption on the skin had become rapidly worse during the week, and on her admission to hospital she was in the most pitiable condition. She was extremely ill, with a very feeble pulse and a high temperature (101° F.). Her face presented a shocking appearance; it was covered with bullæ, many of which had become confluent and had burst, leaving much of the skin of the face, and of the eyelids especially, covered with masses of dried incrustation, which was black from previous extravasation of blood. There were bullæ, very numerous, on the arms, hands, and legs answering in all respects to those of pemphigus, some with opaque white contents and others with reddish contents. The front of the body, the back, the buttocks, and the vulva were in a most unusual condition. It was evident that the bullæ on the body had been very numerous, that they had become confluent, and that the epidermis had given way, leaving the true skin exposed. This was especially the case on the back and buttocks, the whole surface having become one large sore. There was a copious bullous eruption on the arms, the front of the body, and the back of the neck. The stench emitted by the exposed cutis was most offensive. The eyelids were so swollen and covered with black incrustations that the patient was unable to open them. Her state was one of the utmost gravity and at the time of her admission appeared hopeless. She was at once carefully placed in a warm boric acid bath, by which means the exposed surface of the skin was cleared and the stench arising from it destroyed, while the eyelids were bathed freely with warm boric acid solution. On her removal from the bath she was wrapped in cloths soaked in a 10 per cent. solution of boroglyceride. She was ordered as much milk and strong beef-tea as she could take, with two eggs beaten up and ten ounces

Digitized by Google

of port wine. A mixture of quininæ hydrochloras (five grains) and liquor arsenici hydrochloridi (five minims) was ordered three times daily. Under this treatment the patient's condition greatly improved, and two days later dressings soaked with olive oil were substituted for those steeped in the boro-glyceride solution. By this time all offensive odour from the skin had been removed. The patient was, however, still extremely weak; her pulse was 120 and her temperature on Nov. 24th reached 103·2°. Between Nov. 21st and 23rd a few fresh bullæ had formed on various parts of her skin, excepting on her face. Her tongue, which had never since her admission been very thickly coated, was dry and the fur was of a dirty-white colour. On the 25th, although a few fresh bullæ had made their appearance on the wrists and over the left hip, the skin on the back had begun to heal and the patient's expression of face had improved. The dose of the liquor arsenici was increased to seven minims and fish was added to the diet. On the 26th she was still very weak and the tedious process of dressing her body and limbs exhausted her greatly. Her pulse was weak; she slept badly, but took nourishment well. Five ounces of brandy were ordered instead of the port wine. On the 28th she was extremely weak and diarrhœa had set in. Two scruples of the aromatic powder of chalk and opium were given in place of the midday dose of the mixture and the diarrhœa ceased. The dose of arsenic was increased by two minims. The temperature, which up to this date had been irregular, reaching on one occasion 103·2°, now became more regular and ranged between 101° and normal during the next three weeks, after which it fell to normal, the pulse-rate during the same period averaging about 110. On the 29th decided improvement had taken place, and the extensive ulcerated areæ on the back and buttocks and the smaller ones on other parts of the body showed distinctly the commencement of the healing process; the tongue was cleaner and she slept better. On the 30th the dose of liquor arsenici was increased to twelve minims. Pounded meat was ordered in place of the fish diet, and the brandy was replaced by ten ounces of port wine on Dec. 4th. The process of healing was proceeding rapidly, the new skin appearing as islets in different parts of the ulcerated surfaces, and on the 7th the skin of the back, which on admission was one large ulcerated surface, was practically healed. On the 9th the patient vomited after breakfast, and a small boil had formed on the right forearm and on the left knee and a "stye" on the left lower eyelid. On the supposition that these complications might be the effect of a too liberal diet it was decided to substitute fish for the meat rather than discontinue the arsenic; the change was productive of the desired result so far as any fresh formation of boils was concerned, although both of the boils suppurated and required incision. On the 12th further improvement had taken place; the skin over the buttocks was rapidly healing, all the other parts which had been the seat of ulceration being now quite sound. The new skin was deeply pigmented. On the 17th a trace of albumin was found for the first and only time in the urine, which had varied in specific gravity from 1014 to 1020. From this date the patient made rapid progress, gained strength and flesh, slept well, and retained her appetite for food. On the 30th it was noted that a small area on the outer side of the left buttock, another on its inner side, and a larger area on the right buttock remained unhealed; but on all of them there were islets of new skin. On Jan. 3rd, 1896, the healing had so far advanced that the only ulceration which remained was on the right buttock, to which unguentum zinci was applied. Recovery was now uninterrupted and the patient left on the 29th for the Atkinson Morley Convalescent Hospital with only a small unhealed surface on the right buttock.

CASE 2.—A boy two years of age was admitted into St. George's Hospital on Christmas-eve, 1895. He was one of four healthy children, one (a twin) having died from an injury at his birth. The family history was good; there was no history of syphilis in either parent or rheumatic history, and up to the date of the disease for which he came under treatment the child had not been ill. About five weeks previously to his admission a cat had scratched the palm of his left hand and had caused a wound which became so bad that a linseed poultice was applied to it and subsequently an ointment. When admitted to hospital the wound on the palm of the hand had quite recently healed and some dry flakes of dead skin were still adherent around the cicatrix. Three days before he came under observation in Crayle Ward he had been brought to Dr. Rolleston as an out-patient to be treated for an eruption on his legs which in some respects resembled impetigo. The eruption increased and the mother again brought him to the hospital. On examination of the child there was found a copious eruption of pemphigus, the hands, feet, thighs, ankles, and calves being most affected. The child was very ill, with a temperature of 101° F. and a pulse of about 140; the urine was natural. There was no evidence of visceral or other disease. The treatment at once adopted was liquor arsenicalis in minim doses three times daily. The affected skin was carefully washed with a 10 per cent. solution of boro-glyceride, and subsequently enveloped in dressings soaked with olive oil. The diet consisted of milk, beef-tea, and boiled custard. On Dec. 26th some fresh bullæ had made their appearance in front of the left ankle, and the contents of one large one on the outside of the ball of the left thumb had become turbid. On the 27th there were fresh bullæ on both thighs, one on the outer side of the left forearm and a few over the pubes; the older ones were desiccating. On the 28th two fresh bullæ had formed on the right knee (the inner side) and two on the outer side of the left knee. The dose of liquor arsenicalis was increased to two minims. On the 29th there were seen one or two fresh bullæ scattered about the extremities. On the 30th there occurred still further development of the eruption over the pubes, the left knee, and the thigh. Some of the bullæ on the palm of the right hand had burst, and many of those in other situations had turbid contents. The dose of liquor arsenicalis had by this time been increased to five minims three times daily, but in spite of this large dose a few fresh bullæ had appeared. On the 31st the child was restless and vomited three times after food; only a few fresh bullæ had formed. It was thought that the vomiting might be due to the arsenic. Parrish's chemical food was therefore substituted for it, with the result that on Jan. 3rd, 1896, thirty fresh bullæ had formed on one leg and fifty on the other. The gastric disturbance had passed off and the arsenic was resumed on the 4th in three-minim doses three times daily. After this the rapid formation of bullæ gradually ceased, and from the 9th to the 16th there was no increase in the eruption. On the 6th and 8th the child was placed for ten minutes in a bath containing boric acid, with the view of disinfecting the bases of such bullæ as had burst. On the 7th vomiting recurred once after food, but the child had greatly improved in spirits and appearance. With the exception of recurrence of the vomiting on the 12th and 13th progress was very satisfactory till the 16th, when he became irritable and restless, but was much more comfortable after another boric acid bath and a dose of grey powder. All went well and the skin was fast approaching a healthy condition until the 19th, when a large bulla formed on the back of the left hand. The child's diet had been gradually increased by the addition of pounded meat, eggs, custard, milk, and pounded chicken, according to his appetite. On the 27th the child was fretful and his appetite failed; it was with difficulty that he could be persuaded to take any food. Two days later there formed over the external malleolus of the right ankle a large bleb which burst and was dressed antiseptically. On Feb. 1st the portion of skin on which the bleb was began to slough. The child had become seriously ill, rapidly failed in strength, and died on the 11th. The treatment was chiefly by arsenic, and at the last the liquor arsenicalis was given in Parrish's food.

BACTERIOLOGICAL EXAMINATION BY DR. S. RUSSELL WELLS.

Dr. C. Slater being absent from London the bacteriological examination of Case 2 was undertaken by Dr. Wells and conducted in the bacteriological laboratories of St. George's Hospital and the British Institute of Preventive Medicine. A diplococcus has been described as occurring in cases of acute pemphigus by Demme,[1] and Claessen,[2] and recently in this country by Bulloch,[3] while Dühnhardt[4] found a similar organism in a case of chronic pemphigus. Almquist,[5] also, from his investigations considers a coccus that forms a yellow growth on culture media to have been the cause of an epidemic of pemphigus in young children. It was therefore thought advisable to investigate the bacteriology of this case, so on Dec. 24th, 1895, agar, gelatin, and bouillon tubes were inoculated, with due antiseptic

precautions, from the contents of the bullæ on the child's legs, a separate bulla with clear contents being used for each tube. The bouillon and agar tubes were left in the incubator at 37° C., and next day in three out of the four tubes used a growth was found. The gelatin tubes which were left at a lower temperature showed no growth. From the agar and bouillon cultures agar and gelatin plate cultures were made; the gelatin plates were found to be most unsuitable, as the organisms grew so very slowly on this medium at the lower temperature necessary for the gelatin. From the agar plates the three following distinct organisms were separated: 1. A sarcina which presented all the characteristics as to appearances, growth, and staining reactions of sarcina lutea. As this organism is well known to frequent the human skin, and as subsequent experiments showed the sarcina was found to be harmless for guinea-pigs, it was considered to be simply a contamination. Its appearances and effects on guinea-pigs were carefully investigated in view of the yellow pemphigus organism described by Almquist. 2. A small sarcina which formed tiny, almost transparent colonies on agar and grew very slowly. This organism was found to have no effect on guinea-pigs and was also considered to be a contamination. 3. A coccus usually found arranged as a diplococcus. This organism was probably the same as that found by Demme, Claessen, and Bulloch in cases of acute pemphigus. The first two organisms may probably be disregarded, but it will be necessary to describe the diplococcus at length. Cover-glass preparations were made from the contents of the bullæ direct, and showed, on staining with methylene blue, gentian violet, and other like dyes, a few diplococci which presented all the appearances (described below) of the diplococci isolated from the serum of the bullæ. The blood and urine of the patient were not examined and no more tubes were inoculated, as shortly after the cultures were made most of the bullæ broke and were treated with olive oil, so the child's legs, on this account, and from the fact that he passed his urine in the bed, could not be rendered even approximately aseptic.

Necropsy.—The child died on Feb. 11th and the necropsy was made twenty-four hours after death by Dr. Cyril Ogle. His report in the post-mortem book of St. George's Hospital is as follows. "There were no signs of rickets. The body was well nourished. A great deal of superficial scarring was present, chiefly on the legs and the inner side of the thighs. Besides the worm-eaten appearance produced by the scars there was a decided increase of pigment of the skin. Just below the ankle was a large sloughy ulcer covered with iodoform. The body was very anæmic and sallow, but not œdematous. Rigor mortis was present. The height was 2 ft. 6 in. The blood was more fluid than in health. The pleural cavities contained a few ounces of blood-tinged serum. The right lung weighed five ounces and the left four and a half ounces. Throughout the substance of both lungs were numerous small hæmorrhages of about the size of hemp seeds, impalpable, evenly distributed, and where they abutted on the surface there was no pleuritis. The rest of the lung was healthy but somewhat distended; there was no broncho-pneumonia. The tubes were not choked. The pulmonary artery contained a little post-mortem clot. No thymus gland was observed. The heart weighed four ounces. There was no engorgement of the right side. The valves were all sound. There was a somewhat hypertrophied right ventricle with a little dilatation. The foramen ovale was closed. No staining of the endocardium or aorta was seen. There were no hæmorrhages on the surface of the heart. The peritoneal cavity contained about one and a half ounces of clear serum. The liver weighed seventeen ounces and was firm and healthy. The stomach contained much curdled milk in solid lumps. There was no evidence of any gastritis. The pancreas was normal. The spleen weighed one and a half ounces and was firm. The kidneys each weighed two ounces and were pale and healthy; no petechiæ were present. The adrenals were healthy. The mucous membrane of the bladder was spotted with fine hæmorrhages; there was no cystitis. The testes were in the scrotum, which was œdematous. There was no œdema of the legs. The intestines were quite healthy; the mesenteric glands were not enlarged. The brain weighed forty-two ounces; no softening, no distension of the ventricles, no meningitis, and no blocking of the veins were present; the substance was healthy and firm, and there were no petechiæ." Microscopical sections were made of the lungs and stained by Czinzinski's method with eosin and methylene blue, when it was found that there were small extravasations of blood into the alveoli, and in the neighbourhood of these hæmorrhages a few diplococci were found similar to those described below. No other micro-organism could be detected in the sections.

Bacteriological experiments.—The organism, as seen in pure cultures, was a micrococcus of about 0·8 to 1·5 μ in diameter; single cocci were seen, and very short chains of three or four cocci; but by far the commonest arrangement was in pairs, and that this was the natural arrangement was shown by the fact that nearly all those found in the tissues and blood of inoculated animals, and in the fluid of the bullæ, as well as the vast majority in bouillon cultures, examined by the hanging-drop method, were diplococci. The opposed sides of the two cocci were somewhat flattened, so they appeared slightly wider than they were long. No capsule like that of the pneumococcus could be detected. They stained readily with methylene blue, gentian violet, and also by Gram's method. On agar plates the diplococci grew rapidly at 37° C. Well-marked colonies often appeared in twenty-four hours; these had at first a circular outline, slightly raised in the centre, and of a milk-white colour. If kept at 37° C. and prevented from drying these circular colonies increased in size for about a week without changing their form; after this they commenced to throw out slight projections at the edge, so that a colony from ten days to a fortnight old had a rosette appearance, behaving in the same manner as the diplococcus described by Demme. As the age of the colonies advanced they sometimes took on a slight yellowish tinge, changing from a milk-white to a cream colour. The diplococci grew very quickly on agar at 37° C. both as streak and stab cultures, in the latter case in the well-known nail-like form. As a rule there was a copious growth resembling a streak of rather thin white oil paint along the course of the needle in twenty-four hours. At 22° C. the growth on agar took place, but was very slow. On gelatin at 22° C. the growth was extremely slow and feeble, being far slower than on agar at the same temperature; but when the gelatin was liquefied and kept at 37° C. the diplococci grew fairly well, and when, after having been started for twenty-four hours at 37° C., the tubes were allowed to cool so as to set the gelatin and then placed at 22° C. the gelatin was slowly liquefied after several days. It may be mentioned here that gelatin appeared to be one of the worst soils on which to grow the organism; it grew better on almost any other medium at the same temperature. On blood serum the diplococci grew as on agar. In bouillon they grew very rapidly at 37° C., giving rise first to a turbidity and then to a white sediment; in some cases a pellicle formed, but this soon sank to the bottom of the tube. The organisms grew in bouillon at 22° C., but much less rapidly. On potato they formed a whitish, semi-transparent pellicle. Milk was curdled slowly at 37° C. Anaerobic cultures were tried on agar (sloping and stab), bouillon, and potato, and in all cases there was growth at 37° C., but not so rapid as under aerobic conditions, and the colonies were smaller and less dense. Mice and guinea-pigs were subcutaneously inoculated with small quantities of young pure bouillon cultures of the organism, and other mice and guinea-pigs were "vaccinated" with young pure agar cultures. The *modus operandi* in the latter case was to shave a small area of the skin of the animal's abdomen and then to wash the place with strong carbolic acid solution and dry with sterile cotton wool; next to scarify the skin with a sharp sterile scalpel and to rub in a small quantity of the culture with a sterile platinum wire; and after this the place was protected by dry sterile cotton wool and collodion. All the animals inoculated or "vaccinated" with the organism died in from four to eight days, and the diplococcus was recovered as a pure culture from the heart's blood in each case. In the case of the mice, cover-glass preparations made from the heart's blood showed large numbers of diplococci; in the blood of the guinea-pigs only a few were found, but no other micro-organism was present. The only post-mortem appearances of importance were slight enlargement of the suprarenal capsules and very fine hæmorrhages in the lungs of a similar character to those found in the lungs of the child. In these patches a few diplococci were found. No bullæ were produced.

Summary.—From the above it will be seen that the following points have been established: (1) that a diplococcus answering in every respect to that found by Demme, Claessen, and Bulloch was found in the contents of the bullæ of the child during life; (2) that this diplococcus was

Digitized by Google

grown from the contents of the bullæ and obtained as a pure culture outside the body; (3) that after the death of the child a similar organism was found in the lungs and minute hæmorrhages were found in the alveoli; (4) that pure cultures of the diplococci, after having been grown for many generations outside the body, when introduced into the system of either guinea-pigs or mice by hypodermic injection or "vaccination" caused death; (5) that after death the diplococci were grown as pure cultures from the blood of these animals, and that these cultures killed other animals; (6) that the appearances found in the lungs of these animals were comparable to those found in the child's lungs; and (7) that the diplococcus was found in sections of the lungs of the animals. The following conclusions have been drawn. Since bullæ have not been produced in the animals we cannot say that the diplococci found were the cause of the disease, but as this organism has now been found by four independent observers in cases of acute pemphigus, we think, in the light of our results, that there is a strong presumption in favour of this being the case. Demme only obtained pneumonic patches by injecting the organism into the lungs of guinea-pigs, so our results with subcutaneous injections carry the matter a stage further. It is interesting to note that Sahli has described a case in which pemphigus followed broncho-pneumonia. It is possible that the difference in the texture and structure of the skin in the human being and the guinea-pig may account for the absence of eruption in the latter case. We have to thank Dr. Hewlett for performing the injections and "vaccinations" for us, and Dr. Macfadyen and Dr. Slater for the use of their laboratories.

Remarks by Dr. WHIPHAM.—If only on the ground of the great severity of the disease these two cases would have been interesting. The bacteriological observations, and one or two other points which seem worthy of note, render them, perhaps, sufficiently important to merit publication. In Case 1 the extent of the eruption and the great damage to the skin, which was its consequence, are exceptional even in acute pemphigus. On admission almost the whole of the skin of the back, the whole of the skin of the right buttock and of the lower half of the left of the labia majora, and of the back and inner surface of the right arm was extensively and deeply ulcerated after the confluence of the eruption. Equally remarkable is the recovery of a person from so severe a lesion to an organ so important as the skin, the patient being at the time in a condition of such extreme debility and prostration that there seemed to be but one possible termination to the case. The treatment by arsenic was adopted in both cases, and the improvement, which in either case followed immediately upon its administration, goes to prove the accuracy of the observations made some years since by Mr. Hutchinson. A change for the better occurred in the case of the woman within forty-eight hours of her taking the first dose of the arsenic. In the case of the child the formation of the bullæ was very greatly checked in about the same time, and on the sixth day from his admission only one or two fresh bullæ had formed in the previous twenty-four hours. It will be seen in the report of the case that on Dec. 31st (the seventh day from his admission) the child was restless and vomited, and that in consequence the arsenic was withheld, with the result that during the next twenty-four hours thirty fresh bullæ had formed on one leg and fifty on the other. The gastric disturbance having subsided in the course of three days the arsenic was resumed and the development of the eruption was again checked. It is difficult to resist the conviction that we had here an instance of cause and effect. These two cases will add to a very interesting series collected by Mr. George Pernet in a paper which he read in the Section of Dermatology at the annual meeting of the British Medical Association in July, 1895. Mr. Pernet's cases showed that in a very large proportion of them acute pemphigus had followed an injury or wound of the skin. In our cases the woman had a spot on her finger, which she rubbed, then washed some clothes, and, as she described it, "poisoned the place." This possible infection occurred one week before the onset of the pemphigus. The child was scratched by a cat five weeks before he was received into hospital, and the wound had been so bad in the interval that it had barely healed at that date. The probability is that, as Mr. Pernet suggests, a micro-organism was introduced by the injury in each case, and the suggestion derives much support from Dr. Russell Wells's careful bacteriological experiments.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Spontaneous Dislocation of the Hip, with some Remarks on a Class of Case often mistaken for Rheumatism.—A Method of obtaining a complete Skin Covering after Ablation of the Breast.—The Transplantation of Skin Flaps for the Filling up of considerable Defects after Amputation of the Breast.

AN ordinary meeting of this society was held on April 28th, the President, Dr. DICKINSON, being in the chair.

Mr. BARWELL read a paper on Spontaneous Dislocation of the Hip, with some Remarks on a Class of Case often mistaken for Rheumatism. The patient was a naval officer who, on account of an obscure affection of the hip, had been sent from St. Leonards by Dr. Fennings for Mr. Barwell's opinion. He had served for the last three years in Chinese waters and during the homeward voyage was greatly troubled with boils; these culminated in erysipelas of the face while he was passing through the Red Sea. He was landed at Malta and went into hospital, where several sores and some abscesses formed about the face, accompanied with high temperature. One night he was attacked with severe pain in the right hip and thigh, and when he left his bed he was very lame. This pain was ascribed to sciatica and was treated accordingly. He came under Dr. Fennings's care on Oct. 8th still suffering from pain and lameness, his temperature ranging to about 100° F. A striking feature in the case was that the pain was felt in the anterior crural nerves as much as in the sciatic nerve. Mr. Barwell, on first seeing him, noticed the peculiar and uneven step indicative of hip mischief: as the patient stood on the left foot he placed the right one a good deal in front, keeping the knee bent and the body bowed; when standing on the right foot the other heel did not reach the ground by a considerable distance; and the prominence of the trochanter was absent from its normal place. Dislocation of the head of the femur being diagnosed, it was decided to make an attempt to reduce the deformity by Bigelow's method. This was successfully accomplished under full anæsthesia. When internal rotation and adduction had been carried pretty far the head of the bone re-entered the acetabulum with an audible and perceptible snap. The limbs then became of the same length. Three days later the patient walked without any limp; all his pain had disappeared. On Feb. 22nd, 1896, he walked perfectly straight and without limp. Occasionally he had a little vague pain in the upper third of the outside of the thigh. He had been examined at the Admiralty and passed again to active service.—Dr. JOHN HARLEY referred to the case of a young woman who was admitted to St. Thomas's Hospital under his care with acute rheumatism. The disease concentrated itself in the right shoulder-joint, giving rise to swelling and obscure fluctuation there. Later spontaneous dislocation of the shoulder-joint occurred. It was easily reduced, the arm bound up to the side, and the elbow supported. The result was a good recovery. Such a case showed that surgeons should not too quickly interfere in cases of joint affection which might get well of themselves if left alone. In some cases of pyæmia complete absorption of pus from joints might occur.—Dr. NORMAN MOORE said he wished for more information regarding dislocation of the hip-joint in cases of enteric fever. He had read all the post-mortem accounts at St. Bartholomew's Hospital since the year 1867 and no case had been met with, neither had he seen the condition in the wards. He asked if the cases Mr. Barwell had referred to occurred in children or adults, and whether the diagnosis of enteric fever was beyond question, for the recognition of typhoid fever was often by no means certain.—Mr. BARWELL, in reply, said that the case quoted by Dr. Harley was not analogous, for it was a suppurative affection. He had seen three cases of dislocation of the hip in undoubted enteric fever, and in a fourth case there was strong reason to believe that the disease was typhoid fever. In one case, in a girl aged nine years, he attempted reduction two years after the dislocation, but failed. In the case of a girl aged sixteen, in which the diagnosis was confirmed by Murchison, he attempted reduction about four months after dislocation, but failed. In this class of case there was no

Digitized by Google

sign of inflammation in the joint, but the bone slipped on to the dorsum ilii from a healthy socket. The vague pains about the limbs in these cases were not rheumatic, but due to the absorption of some poison.

Mr. MAYO ROBSON read a paper on a Method of obtaining a Complete Skin Covering after Ablation of the Breast. He remarked that in complete ablation of the breast and of the skin covering it a difficulty frequently arose when the effort was made to obtain a skin covering, this being as a rule impossible without further operative treatment. So far as he could ascertain the general practice among surgeons had been to draw the parts together as far as possible and then to leave the remainder to granulate or to cover the remaining surface by Thiersch's skin grafts, the former being a tedious and the latter an uncertain and not always successful method. He showed that by means of one or two single incisions with sliding of the flaps, the whole of a very extensive wound might be closed, and that primary union might thus be secured. Although some tension was necessarily present the observance of antiseptic precautions had prevented sloughing, and in a number of cases on which he had operated he had not experienced any trouble. He concluded his remarks by saying that he believed it would be found that the adoption of the method portrayed, or some modification of it which would carry out the principle of completely re-covering the large wound surface, would not only render these extensive operations less formidable by shortening the convalescence, but would tend to greater thoroughness, as it would also enable surgeons to operate on cases otherwise hopeless. The paper was illustrated by photographs of cases and by diagrams.

Mr. BUTLIN, with whom was associated Mr. BEADON ADAMS, read a paper on the Transplantation of Skin Flaps for the filling up of Considerable Defects after Amputation of the Breast. In cases in which it was necessary to remove large areas of the integument in operations for cancer of the breast, rapid healing of the wound and subsequent contraction might often be prevented by transplantation of flaps of skin in the immediate neighbourhood of the wound. He had employed this method in fifteen or more cases and had generally employed the method of transplantation by rotation. The flaps should not be more than three and a half or four inches in length. They should have large bases. Flaps were more easily procured on the lower margin of the wound. Asepsis was not the only condition necessary to ensure the vitality of the flaps. The best cases for transplantation and the best scheme of transplantation for the majority of cases were discussed. Mr. Butlin had found that tension on the flaps was of comparatively small importance in determining sloughing.—Mr. W. G. SPENCER said that for nearly all cases in which there was not enough covering after removal of the breast the lower flap should be undermined to a much greater extent than was commonly done. The undermining could be carried down to the lower ribs and behind to the angle of the scapula. This not only gave an extraordinary amount of room, but in this way ulceration of a flap was avoided from the twisting of its pedicle. The undermined flap might if necessary be button-holed at its lower portion to prevent accumulation of blood.—Mr. WATSON CHEYNE said that he was able to confirm the last speaker's observations. He always removed a large amount of skin in amputation of the breast—all that which lay over the prominence of the breast. At first in these cases he performed skin-grafting, but afterwards he found that undermining was a better procedure. He carried this out in all directions, quite up to the neck and down to the abdominal muscles, and he drew the edges together with stout silver wire passed at a distance of about an inch from the edges of the flaps. The only condition necessary to enable this manœuvre to be carried out was that the wound should be oval. The stitches of relaxation would sometimes cut through, but this made no material difference to the result. In about 10 per cent. of the cases in which stitching together by these means could not be done he had employed flaps and skin-grafting. An objection to the operation by flaps was that the patient was already often collapsed after an extensive dissection of the region of the breast, and the plastic proceeding certainly added considerably to the length of the operation. In such cases, where collapse was present, he stitched the wound together as much as possible, and then in three or four days skin-grafted the remainder of the wound. Cases treated in this manner did very well indeed, and he had very few failures after skin-grafting.—Mr. WALLIS remarked that in plastic operations about the face he had seen the flaps become very congested and threaten to slough, but this had been prevented by multiple pricking of the flap. The objection to the application of this method to the breast was that it involved the exposure of the wound.—Mr. BARWELL said that he was in the habit of using large lead button sutures where the tension was greatest, and he frequently relieved the stretching by making incisions parallel to the wound edge and then sewing these latter up in a direction at right angles to the wound edge. As he believed that the resistance was chiefly in the subcutaneous tissue he was careful to divide any prominent fibrous bands that presented themselves.—Mr. BOWLBY said that the patients appeared to suffer more pain when the flaps were dragged together and that the patient was more hidebound with the dragging than with the flap method. Cases in which the tumour extended towards the clavicle or towards the sternum were more suitable for flaps, while the wounds extending towards the axilla came together better by dragging.—Mr. MAYO ROBSON, in reply, said that it was only in the exceptional cases that he used the flap method, and he agreed that in all cases undermining and dragging were better where possible, taking care that in all cases where dragging was resorted to the stitches should be placed well away from the edge of the wound. In his flaps he took the whole thickness of the tissue, and he had done it in stout people as well as thin ones without producing sloughing. He used no drainage whatever.—Mr. BUTLIN, in reply, said that his flaps appeared to be much like Mr. Mayo Robson's except that in very fat people he thought it better to take skin only. The flap method avoided the necessity of skin-grafting, which was to the patient a second operation. The after-contraction by the flap method was small, and the upper extremity could be moved with ease.

MEDICAL SOCIETY OF LONDON.

Suppurative Affections of the Mammary Gland.

AN ordinary meeting of this society was held on April 27th, Sir JAMES CRICHTON BROWNE, President, being in the chair.

Mr. MARMADUKE SHEILD read a paper on Suppurative Affections of the Mammary Gland. The paper is published in full in another part of our present issue.

Dr. W. S. A. GRIFFITHS said that it was the business of obstetricians to prevent the formation of mammary abscess, and in this they had been very successful, as the statistics of a hospital like Queen Charlotte's would show, where, under suitable treatment by antiseptics and cleanliness, the affection had almost disappeared. Abscess of the breast was usually associated with some structural lesion of the surface rather than with an affection of the ducts, and for this reason all erosions of the nipple in suckling women should be treated with rest and antiseptics. The new point in Mr. Sheild's method of treatment was to close the original incision and carry on the drainage from the dependent point only. He was under the impression, though he was not prepared to quote his authority, that recent researches tended to show that the breast was not to be regarded as a specialised sebaceous gland.

Mr. F. C. WALLIS said that in acute mammary abscess occurring during lactation he adopted the method of scraping out with the blunt spoon and then thoroughly mopping out with dabs of perchloride of mercury. The hour-glass shaped abscess was not commonly recognised, and this certainly explained the tardy recovery of some cases after incision.

Mr. W. M. ECCLES asked if Mr. Sheild had met with gumma of the mammary gland. He had recently seen a case in which, under iodide of potassium internally and scraping locally, rapid healing had followed. He inquired what treatment was to be adopted in cases of chronic sinus after mammary abscess. The early recognition of pus was extremely important, and he asked Mr. Sheild's views upon the best way to discover pus in the deeper portions of the gland. In cases of mammary abscess a general anæsthetic should be given in order to permit of thorough exploration and treatment.

Dr. A. ROUTH desired to emphasise the importance of preventive treatment in these cases. Some years ago he was in medical charge of an establishment in which many primiparæ were confined, and there mammary abscess was

Digitized by Google

common owing to careless nursing. He then adopted the method of washing the nipple with a weak solution of sulphurous acid (1 in 10) after suckling, the nipple being again washed before the infant was put to it. With regard to the occurrence of diarrhœa and vomiting in children, in some such cases he had found the milk in the superficial part of the breast ducts to be teeming with micro-organisms. To prevent the diarrhœa it was necessary to draw off the first part of the milk with the breast pump and then put the child to the breast. Pressure of a breast bandage upon the nipple might tend to produce mammary abscess.

The PRESIDENT remarked that he had often seen puerperal mania of an acute type associated with abscess of the breast. This might be due either to traumatism or be a part of a general septic process.

Mr. SHEILD, in reply, maintained that though those present might be in the habit of treating mammary abscess by a dependent incision, yet that habit was not generally followed by those in general practice, nor was it advocated in the text-books. Gummata of the breast as a rule did not break down into abscess, but rather tended to form sloughs; he had notes of four such cases. In the treatment of chronic sinus of the breast he advocated thorough scraping, with fixation of the arm to the side, and if that failed the excision of a wedge-shaped portion of the mamma, together with the sinus as well. In the case of an inflamed breast where there was elasticity with œdema of the skin he would examine under a general anæsthetic rather than wait for fluctuation. He had only met with notes of one case in association with puerperal mania, but he had not looked up any asylum records.

PATHOLOGICAL SOCIETY OF LONDON.

Discussion on the Anatomical Results of the Radical Cure of Hernia.—Stricture of the Sac of a Femoral Hernia.—Oxalate of Lime Calculi in Pancreatic Cyst.—Chondro-sarcoma of the Humerus following Fracture.—Angina Pectoris with Thrombosis of Basilar Artery.

AN ordinary meeting of this society took place on April 21st, Mr. BUTLIN, President, being in the chair.

The PRESIDENT introduced a discussion on the Anatomical Results of the Radical Cure of Hernia. He said that during the last ten years this operation had become common and many hundreds had now been performed. It was therefore time to begin to look for the actual results of the operation where death had happened some time subsequently, and he hoped that this discussion would be the opening of a pathological aspect of the subject of radical cure of hernia. The patient was a boy three years old who suffered from an inguinal hernia on the right side. The operation was performed on May 29th, 1895. The inguinal canal was exposed through an incision in its long axis, and a thin sac was discovered, which extended down to the tunica vaginalis, but did not open into the cavity of the latter. When the sac was opened clear fluid escaped. This drew attention to the abdomen, from which fluid could be squeezed freely out through the open sac. The surface of the sac was found to be studded with miliary tubercles, and a mass of tuberculous material was dissected away from the back and upper part of the testis. The sac was separated from the surrounding tissues, twisted up as far as the internal ring, transfixed at its neck, tied in two halves with catgut, and the stump was fastened upwards and outwards to the under aspect of the wall of the abdomen. No attempt was made to reconstruct the inguinal canal after Bassini's method. The child made an excellent recovery and the wound healed by the first intention in spite of the presence of tubercle. The abdomen shrank after the operation. In July the boy was attacked with tuberculous disease of the hip, in which an abscess formed. On Dec. 17th he exhibited the first signs of tuberculous meningitis, from which he died in five days. The seat of operation presented the following characters. At the site of the internal abdominal ring, seen from its peritoneal aspect, was a small mass of pigment. There was no pocket or depression, and, indeed, no sign from which it could have been inferred that a hernia had ever existed. The inguinal canal was practically obliterated.

Mr. GOLDING-BIRD showed a Specimen from a man who had died five days after the Radical Cure of Hernia had been performed by Macewen's method. A double interest attached to the case, as not only did the specimen exhibit the thoroughness of the obliteration of the hernial sac and its final position under the general peritoneum near the inner ring, but also it showed that the case had been one of infantile hernia, the scrotal hernia occupying a place in a well-developed mesorchium from which the testis freely depended into the general cavity of the tunica vaginalis. It was known that extreme force had been used to effect reduction before the patient came under observation, and at the necropsy it was discovered that a small knuckle of bowel had been forced through a slit in the neck of the scrotal sac and had become almost gangrenous. At the operation the scrotal portion of the hernia was easily reduced by taxis, the operation of radical cure being at once after this undertaken, but the fact of a small knuckle having previously been forced through the neck of the sac was unknown, and that condition quite unsuspected, hence the fatal result. The collapsed state of the patient after the operation precluded the possibility of further surgical exploration, nor were the symptoms such as to indicate that bowel still remained unreduced. The symptoms pointed to general peritonitis alone.—Mr. EVE said that it did not matter how the neck of the sac was dealt with so long as the peritoneum was well separated up to the abdominal ring; it was certainly unnecessary to dislocate the twisted or ligatured neck of the sac from its usual locality. He regretted that no specimen was shown to exhibit the result of suturing the conjoined tendon to Poupart's ligament. In twenty cases he had employed silk-worm gut to fasten the conjoined tendon to Poupart's ligament and in none of them had suppuration ensued.—Mr. JONATHAN HUTCHINSON, jun., said that a few days since he cut down on an old case of hernia in which radical cure had been performed. A sinus remained, and at the bottom of this he had found a silkworm gut suture. There was no doubt that silk, however prepared, sometimes acted as a foreign body and induced irritation; it was therefore advisable to use only kangaroo tendon and catgut, which were easily absorbed. He had intended to show a specimen of radical cure of ventral hernia. Death supervened from heart disease five weeks afterwards. The sac had contained the colon and vermiform appendix; the latter was still adherent to the peritoneal scar. He had dissected another case of radical cure of ventral hernia. The hernia was in the right iliac fossa and developed after laparotomy for intestinal obstruction. He sewed up the peritoneum with a catgut suture, and this he believed favoured absence of adhesions afterwards. He had dissected another case of radical cure of hernia; it was of the inguinal variety and a piece of omentum was used as a plug. This was now usually regarded as not only inadvisable but dangerous, as it courted disaster or, at any rate, troublesome symptoms from the band later.

Mr. JAMES BERRY showed a Specimen illustrating Radical Cure of Inguinal Hernia. The patient was a woman aged fifty years who died in St. Bartholomew's Hospital from perforation of a duodenal ulcer. Two years and three months ago an operation had been performed by Mr. Willett for the radical cure of a labial hernia of moderate size. The sac had been tied with silk and cut away and the pillars of the external ring sutured with the same material. The result was excellent. The peritoneum on the inner aspect of the inguinal canal showed a puckered scar, the canal itself was filled up with fibrous tissue, and the external abdominal ring had been obliterated. There was no bulging of any part of the inguinal region.—Mr. W. ECCLES said that in the President's case the peritoneum lining the abdominal cavity showed but few tubercles, and he wondered if the opening of the peritoneum had benefited the child in any way. He had seen the case where a silkworm gut suture caused so much irritation that it had to be removed. The cause of the frequent trouble following suture in this region was perhaps that the parts were in constant movement. He had noticed that patients who had had a radical cure performed and this had failed, found great difficulty in wearing a truss with as much comfort as formerly. This was due no doubt to the use of stout non-absorbent ligatures.

Dr. MACPHERSON LAWRIE (Weymouth) showed a Stricture of the Sac of a Femoral Hernia. The specimen consisted of the distended sac of a femoral hernia. It was oval in shape and measured an inch and a half in chief diameter. The neck of the sac was surrounded by a thin, hard ring, which was about the size of a No. 12 catheter. Above this ring there was a broad fringe of peritoneum, which formed an incomplete upper compartment. The patient was a female aged twenty-one years. Two and a half years before she felt a lump in the left groin after straining. She did not feel the

Digitized by Google

lump coming, but simply found it there. Ever since that it had troubled her a good deal. She was always able to push it up, although sometimes with difficulty. The sac was dissected out, pulled down, and ligatured in three parts without opening. On the distal portion being cut away the proximal end slipped into the abdomen.—Mr. TARGETT said that the specimen was an instance of thickening in the wall of the sac opposite to the saphenous opening, and was probably due to irritation at a point of flexion in the sac. This condition was common in inguinal hernia, but he had not seen it before in a femoral sac.

Mr. S. G. SHATTOCK exhibited Microscopic Sections of Calculi of Oxalate of Lime from a Pancreatic Cyst. So far as he knew, the observation of such calculi in connexion with the pancreas was unique. In herbivora intestinal calculi of oxalate of lime were not rare, but the possibility of the cyst in question being of intestinal or renal origin was disposed of. The cyst was found at the operation by Mr. Pitts to arise from the pancreas, and the contents of it converted starch into sugar. Both chemically and microscopically the calculi were of pure oxalate of lime and precisely like certain urinary forms. Sir Alfred Garrod in 1849 had demonstrated the presence of calcium oxalate in the blood of certain gouty patients and more recent evidence went to show that the oxalate of lime in the urine was ingested as such in vegetable food stuffs. Chemists had not as yet, however, investigated the common secretions for the presence of oxalate. It was not fully known what held the salt in solution in urine; in the case now recorded the absorption of certain constituents from the cyst contents was probably the cause of its slow crystallisation. The only observation bearing at all on the subject was that mentioned and confirmed by Virchow—viz., the occasional presence of octahedra of calcium oxalate in thyroid cysts. Mr. Shattock considered the possibility of the acid having a bacterial source and being due to the access of organisms from the intestine; but whilst most of those isolated from the small intestine produce lactic acid no known bacteria produced oxalic acid. In gelatin streak cultures of bacillus coli communis it was not rare to find the jelly grow slowly turbid beneath the culture; but Mr. Shattock had found that this depended upon the precipitation of a carbonate in the form of minute spheres; whatever the acid was that was elaborated in the growth of bacillus coli communis it was not oxalic. Sheridan Delepine, however, had shown that a formation of oxalate of lime occurred in nutrient gelatin when aspergillus niger was grown upon it with access of air.—Dr. KANTHACK said he had recently examined the fluid drawn from the abdomen of a patient who was presumed to be suffering from ascites. The fluid contained no albumin nor could sugar be discovered by ordinary tests. Microscopically there were a number of crystals of oxalate of lime present. He had found similar crystals in the fluid of an ovarian cyst. There were no micro-organisms in the fluid in either of the cases, and he knew of no micro-organism which could produce oxalic acid.

Mr. S. G. SHATTOCK recounted an instance of Chondrifying Sarcoma following Fracture. The fracture occurred in the humerus of a man from a heavy fall. After five weeks union was complete and the arm felt normal; a month and a half later a swelling was noticed for the first time in the region of the fracture. Disarticulation at the shoulder-joint was performed later. Death took place about two years afterwards with symptoms of recurrence in the chest. Mr. Shattock remarked upon the rarity of the sequence and discussed it, drawing an analogy between this and the rarity also with which bone tuberculosis followed fracture, although after contusions of cancellous tissue both sarcoma and tuberculosis were frequent events. Two possible reasons were suggested. One was the more active cell-processes that ensued after the graver injury and which successfully inhibited the growth of a particulate virus lying in or reaching the part. The other was the function of the red marrow in locating both bacteria and inorganic particles which reached the circulation; a fracture of the middle of a shaft involved adipose medulla; contusions of the ends of the bone involved cancellous tissue, and it was here that any virus would be particularly located.—Mr. BERRY asked what ground there was for believing that the tumour followed the fracture, and suggested that the fracture might really be secondary to the formation of the tumour, and the damage to the bone caused by the latter was the cause of the fracture. A patient came into St. Bartholomew's Hospital with a fracture of the femur. At the necropsy a small secondary epithelioma was found which had eaten away quite two-thirds of the circumference of the shaft, but in that case no tumour at all could be felt during life.—The PRESIDENT mentioned the case of an old man who twisted his leg and broke his femur with the application of but very slight violence. At the post-mortem examination a myeloid tumour was found in his jawbone and in one of the ribs, and the marrow of the bones was noticed to be generally changed in character. There was something in certain of the ends of particular bones which rendered them more liable to malignant disease.—Mr. PEARCE GOULD referred to the case of a woman whose breast was removed for carcinoma five years ago and who sustained a fracture of the right humerus when turning back the bedclothes. He cut down upon the fracture and examined it carefully, but the bone appeared to be normal to the finger. Three months later there was extensive malignant growth in the upper part of the arm. Fracture of the neck of the femur and of the patella occurred through the red marrow, and yet sarcoma following was very rare.—Mr. W. G. SPENCER said that malignant disease might occur in the red marrow apart from tumour, and it should not be forgotten that in the case under discussion the tumour was a chondro-sarcoma of the periphery of the bone and not a marrow growth. Von Recklinghausen had pointed out that those parts of the bone most used near the joints and where the pull of the muscles occurred were more vascular and prone to malignant growths.—Mr. TARGETT said that in confirmation of this it was to be noted that exogenous hydatids selected as sites the vascular epiphysial ends of bone, as at the knee and hip, and in most cases there was a history of accident before the development of the hydatid.—Mr. SHATTOCK, in reply, said that it should be remembered that the sub-periosteal tissue, like the marrow, was extremely vascular, and both were prone to bacterial infection.

Dr. PARKES WEBER showed a specimen of Thrombosis of the Basilar Artery and Atheroma of the Coronary Arteries from a case of Angina Pectoris. The patient was a man fifty-one years of age, who had suffered from syphilis and exhibited crossed hemiplegia. Attacks of angina had come on and had disappeared, and he died ultimately from cardiac failure and ascites. The right coronary artery was nearly obliterated and the left was much contracted by atheroma. There was old thrombosis of the basilar artery and there was also a cyst of the internal capsule.

The following card specimens were shown:—

Mr. J. CLARKE: (1) Multiple Embolic Aneurysms; and (2) Loose Bodies from Sub-deltoid Bursa.

Dr. MORRICE (Salisbury): Deposit of Fibrin upon the Heart.

Dr. FISHER (Clifton): Thrombosis of the Renal Veins in Bright's Disease.

Mr. B. POLLARD: (1) Diverticulum Ilei; and (2) Congenital Occlusion of the Œsophagus.

Mr. GURNEY (Plymouth): Metastatic Sarcoma of Both Breasts.

Mr. TARGETT: Adrenal "Rest" in Kidney.

Dr. HEBB: (1) Carcinoma of the Prostate; (2) Dilated Stomach from Stenosis of the Duodenum; and (3) Hour-glass Contraction of the Stomach.

CLINICAL SOCIETY OF LONDON.

Excision of the Upper Two-thirds of the Fibula for Sarcoma.—Deficient Development of the Lower End of the Tibia after Transverse Fracture.—Sequel to Acute Swellings over the Cranium of an Infant.—Multiple Neuritis of Toxic Origin.—Deficiency of Ribs.—Affection of Speech.—Sacro-coccygeal Tumour.—Adult Rickets.

AN ordinary meeting of this society for the exhibition of clinical cases was held on April 24th, Dr. BUZZARD, President, being in the chair.

Mr. BLAND SUTTON showed a case of Excision of the Upper Two-thirds of the Fibula for Sarcoma. The patient was a woman aged twenty-three who came under his care in November, 1895, with a swelling over the region of the upper end of the fibula. This he cut down upon on Dec. 1st, dividing the musculo-cutaneous nerve and turning its ends upwards and downwards to give him freer access. He excised the tumour with the upper two-thirds of the fibula, being obliged to sacrifice at the same time the anterior tibial nerve and vessels. He then sutured the divided ends of the

Digitized by Google

musculo-cutaneous nerve and closed the wound. Three days afterwards there was sensation in the parts supplied by the musculo-cutaneous nerve. She developed talipes equinus, which had been remedied by means of a suitable boot, so that she could walk without difficulty. The growth was of the nature of a round-celled sarcoma with a thick fibrous capsule.

Mr. GORDON BRODIE showed a case of Deficient Development of the Lower End of the Tibia after Transverse Fracture. The patient was a man twenty-two years of age who was admitted into the Middlesex Hospital twelve years ago for a transverse fracture of the tibia caused by the overturning of a hand-cart, which snapped the bone above the ankle and caused a good deal of bruising about the joint. The patient was unable to recollect the precise spot where the fracture occurred, but placed it well above the epiphysial line. Examination showed that the end of the tibia was dwarfed in its growth, with an inward curve of the lower fourth of the bone, bringing the internal malleolus into strong relief and causing the tibio-fibular mortise to be inclined inwards slightly, thus giving the foot a list inwards. No irregularity could be detected along the anterior border of the tibia. There was considerable hypertrophy of the lower end of the fibula, and its subcutaneous surface was marked by ridges, and projecting from the anterior border of the malleolus was a large boss of bone which made the breadth one inch greater on this side than on the other. In order to compensate for the position the foot was thrown into by the inclination of the mortise there was well-marked valgus, the tubercle of the scaphoid coming out strongly when the patient pressed his foot on the ground. Roentgen's rays revealed that there was absolute continuity of the bone.

Mr. F. C. WALLIS exhibited a patient previously shown, a child who, on the last occasion, presented a large Diffuse Swelling over the Forehead, limited by the sagittal suture, the nature of which could not be defined. Nothing was done in the way of treatment, and some time later the child contracted measles, after which the tumour cleared up, and now not a trace remained.

The PRESIDENT introduced a case of Multiple Neuritis of Toxic Origin which had been shown by Dr. Mott in October, 1893, and he described the case as one of "multiple infective neuritis" in a paper in February, 1894. The patient at that time was brought to the society on a stretcher, being then paralysed in all his limbs. He had been admitted to hospital in April, 1893, with severe symptoms—hæmaturia, melæna, high temperature, &c.—symptoms, in fact, at first thought to point to typhoid fever. Gradually, however, it merged into a condition of paralysis, with marked wasting of muscles, and it was noted that each exacerbation of temperature was followed by an extension of the paralysis. The patient passed under his own care in May, 1894. Various joints had at different times to be straightened under an anæsthetic to break down adhesions. The knee-jerks were exaggerated. He remained in the hospital until February, 1895, by which time he had recovered power in the legs, and power was beginning to return in the upper extremities. There was, however, still some loss of reaction to galvanic and faradaic stimulation in the arm muscles. He was treated by massage, electricity, and hot-water douches. Dr. Buzzard observed that although the symptoms undoubtedly pointed to multiple neuritis, anterior poliomyelitis was also present, as shown by the spasticity of the paralysed muscles. Cultures of blood from the finger taken during an exacerbation demonstrated the presence of a coccus which Dr. Kanthack had been unable to identify.

Mr. J. MURRAY showed for Mr. PEARCE GOULD a case of Deficiency of the Lower Ribs. The patient was a boy aged five, in whom the eighth, ninth, and tenth ribs on the left side were completely wanting, leaving a gap two and a half inches wide. The eleventh rib was smaller than the corresponding rib on the other side, but the twelfth was larger. When he breathed the spleen could be seen moving freely up and down and the diaphragm could be seen rising and falling. There was nothing of interest in the family history. There was no history of any disease of the chest or of maternal impression.—Mr. CLEMENT LUCAS thought the "x" rays might demonstrate the presence of the vertebral ends of the ribs, which were often present in these cases though they could not be felt. The facility with which the spleen could be felt and handled suggested the value of the case for physiological observation.—Mr. MAKINS said that after empyema he had found nearly the whole of a rib gone.

Dr. HERRINGHAM brought forward a case of Curious Affection of Speech. The patient was a boy aged thirteen years who, before he was six years of age, began to speak in a slow and markedly syllabic manner. He had a great deal of difficulty in beginning words except those commencing with labial consonants. He was otherwise intelligent and in good health, had no mental symptoms and no symptoms of disseminated sclerosis. The defect appeared to be more one of articulation. He had, however, two other motor symptoms, viz., "jumps" and "shakes," which consisted of convulsive movements of the hands and shoulders, which came on suddenly, mostly in the morning. He had also twitchings of the muscles of the face. The defect of speech was noticed as soon as he began to speak. He had measles at four years of age, but the parents believed that even before that attack there was something abnormal in his speech. It was not a progressive disease. There were no ocular symptoms.—Dr. ORMEROD recalled the case of a young man who exhibited a very similar defect of speech which came on after an attack of what he called "sunstroke" when in India. He was when first seen still slightly ataxic and his speech exhibited the same syllabic character as this lad, though he had no hesitation in beginning and he always spoke in a monotone. He had seen the man from time to time since, and he presented no motor symptoms and could walk long distances. Dr. Hughlings Jackson suggested, when he brought the case forward, that it was an example of interference with speech associated with ataxy supervening after some acute infective disease. There was no evidence of meningitis.—The PRESIDENT also remembered the patient alluded to by Dr. Ormerod, and he, too, noticed the similarity of the defect. He suggested that it would be a good thing to record these defects by means of the phonograph, because defects of speech really could never be adequately described in words.

Mr. H. H. CLUTTON showed a case of Sacro-Coccygeal Tumour. The patient was a boy aged three and the tumour, which was enormous, had not increased in size since he first came under observation two years ago, but he (Mr. Clutton) had postponed interference on account of the boy's delicate state of health. The tumour consisted mainly of one large cyst with some solid matter round the base, and per rectum a fluctuating swelling could be felt extending up the rectum rather beyond the reach of the finger. The sacrum and coccyx could be felt projecting over the tumour, showing that it commenced between the rectum and the coccyx. He proposed to tap the cyst at the outer part, reserving the question of dealing with the internal cyst till later.—Mr. CLUTTON also showed a woman aged twenty-six with Spina Bifida, the position of which was, of course, outside the sacrum, thus contrasting with the previous case. The swelling was not quite in the centre; the skin over it was thin; it was congenital and showed a depression with hair sprouting from it. It did not increase in size with coughing. Five years ago he saw in a woman of the same age another case of spina bifida which was twenty-three inches in circumference. In both these cases of spina bifida he advised no interference, but the patients, on account of the approach of matrimony and their inability to assume the dorsal decubitus, insisted on the removal of the tumours.—Mr. BLAND SUTTON observed that the result of intervention in pre-antiseptic days had been invariably fatal, but since that time several successes had been recorded. He added that possibly the tumour felt per rectum might not extend as far as would seem. They did not usually extend above the levator ani. The fatality of the earlier operations was due to intervention having been resorted to at too early an age.—Mr. CLEMENT LUCAS said he had operated some time since on a tumour of this kind consisting mainly of two cysts. He first tapped the most external cyst, carefully sealing the wound to prevent infection, and later repeated the operation for the other, and the result was satisfactory. In another case in which the tumour sprang from the front of the sacrum, pushing up the bladder and rectum and giving rise to troublesome symptoms, he made a horse-shoe incision round the anus and cut away the solid tissue in pieces, and that case also recovered.

Mr. SALTER and Dr. HALE WHITE showed a case of Adult Rickets. The patient was a girl aged fourteen years who exhibited in a marked degree the lesions usually associated with rickets. She had been under observation for two years and the joints had been skiagraphed, showing the exact pathological condition. She was admitted to hospital in January, 1894, for genu valgum, which had commenced in September, 1893. Double osteotomy was performed and she was discharged in March, 1894. Since the operation she had never been able to walk on account of the pain in her ankles. In December,

Digitized by Google

1894, she fell and fractured her left thigh, apparently with very slight violence. There was marked atrophy of both vasti interni and general muscular weakness. The bony lesions were not accompanied by any sweating, painful sensations, or restlessness, usually met with in association with rickets in infants, nor did she appear to have had rickets when a child. The disease did not involve the epiphysial line or the epiphysis, but the shaft of the bone above it. — Mr. CLUTTON remarked that there was a distinct ridge at the epiphysial line in the case shown. The skiagraph, of course, would not assist, as the cartilaginous enlargement would not appear in the picture. In one such case, in which there was slight thyroid enlargement, he had given thyroid extract with success.—Dr. COLMAN agreed that the bone changes in the case shown were precisely like infantile rickets. From a case of adult rickets seven years ago he had an opportunity of examining wedges of bone under the microscope, and the changes in that case also were like those seen in early rickets.

Dr. HARRY CAMPBELL showed a typical instance of Acromegaly in a man aged forty-six and he demonstrated that the conditions present were precisely those which obtained in the anthropoidal apes. The occipital crest was marked; there was excessive development of the frontal and maxillary sinuses; the head was prognathous, the lower jaw being underhung. The spinal dorsal curve was exaggerated and the antero-posterior chest measurement increased. The tensor vaginæ femoris was excessively developed and the nails were striated. The eyesight was normal; the urine contained albumin, but no sugar.

EPIDEMIOLOGICAL SOCIETY.

The Mortality and Sickness in Back-to-back and other Artisans' Dwellings in Bradford.

A MEETING of this society was held on April 17th, Mr. SHIRLEY F. MURPHY, President, being in the chair.

Dr. ARNOLD EVANS read a paper on the Mortality and Sickness in Back-to-back and other Artisans' Dwellings in Bradford. These were all "self-contained" and either of the "through-and-through" or the "back-to-back" kind, the latter being in long unbroken rows or in what were inaccurately described as "blocks of four," a passage dividing each two pairs, though only on the ground floor, the upper floors being continuous. "Through" houses had two rooms on the ground floor and two bedrooms, with perhaps an attic, above, a garden in front and a yard in which were the privy or closet and ashpit behind, with a door communicating with a back passage between the parallel streets. Back-to-back dwellings of the older type had a living room and scullery on the ground floor, with two bedrooms above, and each had its yard with privy and ashpit between it and the street; but in those of the newer kind, while one pair were flush with the street the other looked out on to a large yard common to the whole block, with two ashpits and four privies ranged along the further wall, the passages between the blocks giving the occupants of the hinder pair access to the street and those of the front pair to the yard, the purpose of this peculiar arrangement being to secure some amount of cross-ventilation through the scullery windows opening into this passage. Dr. Barry and Mr. Gordon Smith, in their report to the Local Government Board, stated that while the practice of building back-to-back houses, formerly very general in the north, had been almost wholly discontinued in Lancashire and Staffordshire, it still prevailed in the West Riding, and that 64 per cent. of the dwellings of the working classes erected in Bradford between 1876 and 1886, affording accommodation for 20,000 persons, had been of this description, a prohibitory by-law passed in 1862 having been rescinded seven years later, whether through prejudice or considerations of cost and rental it was hard to say, for the effect of the special regulations as to the arrangement of streets, yards, and passages was that actually more ground was required for the new "back-to-back" than for "through-and-through" houses and the saving in bricks and mortar was insignificant. Even a better class of dwellings, which might almost be styled villas, were being thus built, though the defects in the way of ventilation were insuperable, and the scullery window in a covered passage utterly insufficient, to say nothing of the inconvenience and indecency of the position of the privies and their tendency to become a nuisance, or the fact that when streets of such houses ran east and west those on the north side never saw the sun. These points were strongly insisted upon by the late Mr. Netten Radcliffe and Mr. Gordon Smith in their reports, but the building of "back-to-back" houses of both kinds went on till June, 1894, when the decision of Justices Wills and Wright [Travis *v.* Uttley, Q 13], that drains common to several houses were sewers for the maintenance of which the sanitary authority was responsible, induced the corporation to insist on separate drains to each house and put a check on their further erection. Dr. Barry having already suggested inquiries into the relative prevalence of pulmonary and infectious diseases in "back-to-back" and "through-and-through" houses, Dr. Bell undertook the work at Bradford, Dr. Herbert Jones at Shipley and Saltaire, and Dr. Tatham and Dr. Niven in Manchester. Dr. Bell found that the "through-and-through" houses seemed to compare unfavourably with the "back-to-back," and the Manchester houses were in other respects utterly unfit for human habitation; but Dr. Jones found that the mortality from all causes, and from phthisis and infectious diseases and diarrhœa, was greater in back to back houses, other conditions being alike. More recently Dr. Evans, selecting groups of typical houses with occupants of a similar class, fully confirmed the opinion as to their relative healthiness:—

Class of houses.	No. of houses.	Population.	Average persons in house.	Average square yards to each house.	Average houses to acre.	No. of houses to acre.	No. of persons to acre.	Weekly rent, including rates.	Death-rate per 1000. All causes.	Phthisis.	Diarrhœa.
Back-to-back continuous	619	2728	4·4	98·6	24·2	49·0	215·6	4/6–5/9	17·7	2·41	(?)
Back-to-back in fours	1928	9116	4 7	125 0	26 5	38·7	181·89	5/3–6/-	18·3	1 68	0·25
Through houses	751	4002	5·3	116·6	22 0	41·5	219 95	6/–7/6	15·1	1·39	0·29

Of the 45,000 houses in Bradford 20,000 were back to back, and the mean death-rate for the whole borough in the years 1890 to 1892 from all causes was 21·12, from phthisis 1·853, and from diarrhœa 0·540 per 1000. The population of the selected groups was not Irish, but average respectable artisans, alike engaged in a single industry, the manufacture of woollen goods.

Dr. H. F. PARSONS remarked that it was only in the West Riding, where wages were not lower or the cost of building higher than elsewhere, that "back-to-back" houses were still erected, old prejudices dying hard. Leeds, for example, had been the last to adopt any reform.—Dr. HERBERT JONES said they were unknown at Crewe, where 78 per cent. of the houses were rented at or under 5*s.* a week.—Dr. E. F. WILLOUGHBY insisted on the fallacy of death-rates that did not take account of the character of the population, their poverty, and overcrowding as shown in a comparison of the relative health of the occupants of successive storeys in the huge houses in German towns.—Dr. T. M. LEGGE supported this contention from his personal acquaintance with the housing of the poor on the Continent.—Brigade-Surgeon R. PRINGLE could not understand the small average number in the families or the low death-rate from diarrhœa.—Dr. BULSTRODE and Fleet Surgeon PRESTON having made similar remarks, the PRESIDENT observed that though "back-to-back" houses had almost disappeared in London, many of the large blocks, as those erected under the Guinness Trust, were practically such. The report of the London County Council on overcrowding showed that the death-rate from phthisis, diarrhœa, and all causes was in direct ratio with the number of persons to a room.

Dr. EVANS, in reply, explained that in Bradford there was but one industry and very little difference in the social conditions of the population, though, to ensure identity, he had taken districts too small to admit of more minute statistical comparisons.

HARVEIAN SOCIETY OF LONDON.

Some Unusual Swellings of the Parotid Gland.—Prognosis in Chronic Non-suppurative Catarrh of the Middle Ear.—Demonstration of the Roentgen Rays.

A MEETING of this society was held on April 16th, Mr. J. H. DREW being in the chair.

Mr. RAYMOND JOHNSON read a short paper on Some Unusual Swellings of the Parotid Gland.[1]—Dr. CODDE ADAMS said that the subject of parotid swelling was one of extreme interest to those who, like himself, were engaged in general practice. He was struck by the unsatisfactory state of our knowledge as to the etiology of such conditions, and as a result he felt himself frequently compelled to enforce all the annoying measures of isolation and quarantine where he had doubts as to whether the case was really one of mumps at all. This, indeed, had been done in the majority of the cases just described by Mr. Raymond Johnson which were both interesting and instructive. Mr. Johnson, however, had not made reference to the possibility that such swelling might be caused by reflex action. It had been noticed that arrest of salivary secretion always took place in the dog if the intestines were handled. Mr. Stephen Paget had published in the Transactions of the Clinical Society an interesting account of a case of parotid swelling occurring in connexion with, and apparently as a result of, severe fæcal accumulation in the intestine. Mr. Paget had also published a record of no less than 102 cases of parotitis associated with operative interference with the abdominal organs. He (Dr. Adams) had no very defined ideas to lay before the meeting, but he would like to suggest the possibility that many cases of so-called mumps might really be instances of reflex hyperæmia resulting from intestinal indigestion. At all events, he hoped his remarks might assist criticism and discussion.—Dr. DUNDAS GRANT remarked that one of Mr. Raymond Johnson's cases seemed to have improved very rapidly after the application of liniment of iodide of potassium. This recalled to his recollection a case of suppurative parotitis under his own care when in general practice in East London, in which no benefit ensued from even a considerable number of incisions. The late Mr. Chance was called into consultation, and he recommended abstention from all instrumental interference, predicting that under the use of iodide of potassium ointment the condition would speedily come to a favourable termination. This prediction was amply verified, and he (Dr. Grant) thought the therapeutic hint might be found of value by those who met with these decidedly rare cases. He drew the attention of the society to observations which he had made on some cases of mumps in which it was clearly shown that the use of pilocarpin influenced the course of the disease most favourably in contra-distinction to belladonna. Pilocarpin was also the best remedy for the labyrintbine effusion which sometimes produces absolute deafness in mumps.—Mr. RAYMOND JOHNSON replied.

Dr. WILLIAM HILL read a short communication on Prognosis in Chronic Non-suppurative Catarrh of the Middle Ear. He excluded from the purview of the paper cases of only a few months' standing and also more or less chronic deafness in children and young persons, "because these are admittedly the most favourable classes of cases the otologist has to deal with, and the results of treatment are often brilliant and nearly always encouraging; with adults, however, it is frequently quite otherwise." On account of anatomical conformation of the tympanum and its delicate structure it was obvious that when catarrhal changes went on for even only six months permanent damage was likely to result, so that absolute cure could rarely be looked for, and they were fortunate when they could promise and obtain a moderate improvement in condition or even arrest the disease, which is usually progressive. After alluding to the forms of middle-ear catarrh and to the diagnosis, Dr. Hill briefly discussed the more obvious factors which influence prognosis, such as the age and general health of the patient, the duration and degree of the deafness, and the damage done to the membrane, ossicular apparatus, and Eustachian tube; more detailed consideration was, however, devoted to "certain points which are often of distinct aid in forming a prognostic opinion which is something more than a mere guess." The mode of onset was instanced: deafness coming on gradually and almost imperceptibly and resulting in marked dulness of hearing in the course of a year or two was usually due to sclerosis and was incurable; a history of sudden onset was, as a rule, much more favourable, especially when due to a definite cause, such as nasal and pharyngeal catarrhal hypertrophies. Amongst exceptions to this rule were noted tympanic disease or acquired syphilis and cases of extensive destructions produced by scarlet fever and other exanthemata. In this way prognosis was seen to be influenced by the cause. When tympanic trouble is due to throat and nose diseases, provided the aural lesion is not great the outlook is good if the cause can be removed, even when on account of want of ventilation from the blocked tube the impairment to audition may be considerable, and even in long-standing cases the result is occasionally gratifying. Chronic cases of malarial, rheumatic, and gouty origin usually resist treatment. Deafness of dental origin requires early treatment. When no extrinsic cause is ascertainable, as in tympanic sclerosis, the otologist is usually powerless even when the disease has only lasted a few months. Variability in the amount of deafness is nearly always an encouraging sign; it may depend on the general health, on locality, atmospheric conditions, occupation, &c.; in women pregnancy, lactation, menstruation, and the menopause often act adversely. A very hopeful form of variation in hearing power is improvement as the result of the air douche applied through the Eustachian catheter or otherwise, as is also relief afforded by the production of positive and negative pressure in the meatus by Siegle's or Delstanche's methods. Some patients hear better immediately after the introduction of a tympanic bougie, and, again, after fluids have been injected into the middle ear through the Eustachian catheter; when such exceptional results are obtained there is always hope of some permanent relief by a course of appropriate treatment, and the same holds good for pressure applied to some part of the membrane by means of probes and other supports. Tinnitus, paracusis Willisii, and vertigo are generally held to be of unfavourable import, but the prognostic value of these symptoms has probably been over-estimated.—Dr. DUNDAS GRANT expressed his accordance with the views set forth in Dr. Hill's paper. He thought that it was most essential to differentiate between the two classes of cases—the exudative, in which the Eustachian tube was narrowed, and the sclerotic, in which this was not the case, the disease being mainly centred in the articulation between the stapes and the vestibule. He attached great value to the use of Eustachian bougies, and he had found that Weber-Liel's fine gum-elastic intra-tympanic catheter was the most convenient form of instrument to use for the purpose. It is smooth and flexible, and being hollow the fact that it was in the right position could be determined by auscultation He presumed that Dr. Hill would not continue the use of the bougie in cases in which the Eustachian tube was quite free. The prognosis, in his experience, was much more unfavourable in the case of females than that of males.—Dr. HILL replied.

Mr. J. T. LEON and Mr. R. W. DODGSON of St. Mary's Hospital gave a demonstration of the Roentgen Ray Process of Photography.

[1] This was published in full in THE LANCET of April 18th, 1896.

KIDDERMINSTER MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—The Pathology, Symptoms, and Treatment of Some Chronic Urethral Discharges.

A MEETING of this society was held at the Kidderminster Infirmary on April 17th, Mr. W. MOORE, President, being in the chair.

The PRESIDENT exhibited a man with a Rare Form of Eruption on the Back of the Wrist and Side of the Face. Each patch commenced as a small papule and gradually spread; the man attended horses, and the President regarded the case as one of infection.

Dr. EVANS showed a lad upon whom he had operated for Hammer-toe by dividing the lateral ligaments subcutaneously with a very good result.

Dr. EVANS and Mr. J. L. STRETTON demonstrated the use of the Phonendoscope on a case of Bronchitis.

Mr. J. L. STRETTON showed:—1. A large Multilocular Ovarian Cyst with twisted Pedicle removed from a pregnant woman. The patient, aged thirty-seven years, married, had had several children, and was admitted into hospital in April

Digitized by Google

with the following history. She had been a healthy woman until January, but since then she had noticed the abdomen getting larger and she had occasional pain. She had not menstruated since the end of December and thought herself pregnant. Five days before admission she was suddenly attacked with acute abdominal pain and sickness; the abdomen had greatly increased in size, there had been no action of the bowels, and the urine had been drawn off by a catheter. The patient lay on her back. Her complexion was pale. She complained of abdominal pain. The tongue was moist. There was no sickness. The temperature was 99·4° F. The abdomen was considerably distended and tympanitic; it was very tender, especially on the left side. A tumour could be felt extending to the umbilicus, but could not be distinctly palpated owing to the distension. Per vaginam the tumour appeared to be distinct from the uterus. Mr. Stretton opened the abdomen by a median incision. On opening the peritoneal cavity an object like a gangrenous piece of intestine presented. This proved to be a locule of a multilocular ovarian cyst with the pedicle twisted. About five pints of fluid were evacuated and the cyst removed. (The uterus was enlarged to the size of a three or four months' pregnancy.) The abdomen was flushed with boracic solution and closed with silkworm gut sutures. The patient made an uninterrupted recovery. The first dressing was on the seventh day. There was no suppuration or rise of temperature. 2. The Bones consisting of the Lower End of the Humerus, with the Heads of the Ulna and Radius removed by Excision for Tuberculous Disease. 3. Portion of the Right Ramus of the Lower Jaw, with two Molar Teeth and one Bicuspid Tooth, excised for Malignant Disease. The patient was a man aged sixty-four; he had an epithelioma of the lower lip removed by Mr. Stretton last June. There was a lump the size of a small orange firmly attached to the lower jaw, which had been growing for two months. Mr. Stretton excised the growth together with the portion of the ramus and submaxillary gland. The patient made an uninterrupted recovery and was not much inconvenienced. The growth apparently commenced in a gland and spread to the periosteum, and so involved a small portion of the surface of the bone.

Mr. JOSEPH ROBINSON read a paper on the Pathology, Symptoms, and Treatment of Some Chronic Urethral Discharges.

Reviews and Notices of Books.

The Surgical Diseases of Children and their Treatment by Modern Methods. By D'ARCY POWER, M.A., M.B. Oxon., F.R.C.S. Eng., Demonstrator of Operative Surgery at St. Bartholomew's Hospital; Surgeon to the Victoria Hospital for Children, Chelsea; Examiner in the University of Durham; Member of the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England. With Illustrations. London: H. K. Lewis. 1895. Price 10*s.* 6*d.*

THIS work on the Surgical Diseases of Children will doubtless meet with general acceptation by the profession, for, as the author points out in the preface, there are few books in English exclusively devoted to the surgery of childhood. It does not pretend to be more than a guide to those who wish to pursue each subject more thoroughly than can be done in a text-book, but to make it useful the author has been at some pains to verify his references. Mr. Power is already well known for his writings on various subjects of medical interest and he does not therefore appear for the first time as an author. Some years have now elapsed since the last edition of a work such as this, and there has been considerable advance in this department as in other departments of surgery. In intracranial disease and its treatment, for instance, there has been a marked change, and the present position of surgeons as regards disease of the temporal bone and the cerebral inflammations arising from it, the treatment of meningitis of tuberculous origin, &c., is well placed before the reader. Other chapters are deserving of special notice; for example, those which deal with the tuberculous diseases of bones, joints, and synovial membranes, surgical diseases of the air passages, and the operations of tracheotomy and intubation. The work is not, however, without some drawbacks, which will, we hope, be remedied in the next edition. To us it bears the marks of somewhat hasty compilation and in several parts falls short of the ideal text-book. The author excuses his neglect of talipes and its treatment because there is a recent monograph on that subject, but there are few departments of surgery which might not be passed over if this excuse could be accepted for the omission, and the department of orthopædics is one which demands considerable attention in all hospitals devoted to the treatment of children. Lateral lithotomy is not given "because it is described in every text-book in surgery"; but so are the other operations given in the book. He is also inclined to introduce somewhat difficult terms (osteopsathyrosis, for example) to describe certain diseased conditions, for which students will hardly thank him. Mr. Power recommends two forms of silver tube for use after tracheotomy—Durham's and Parker's. These are undoubtedly the best, but it is a little difficult to understand what he means when he recommends later that if blood gains access to the trachea during the operation the two cut edges of the tube may be drawn upwards into the wound and the trachea may be freed, &c.; also when he speaks, without further explanation, of ulceration of the innominate or carotid arteries caused by the pressure of the lower end of the tube the reason is not obvious, for with the tubes recommended there is no fear of this accident. A more detailed explanation as to the insertion of sutures in the radical cure of inguinal hernia is, we think, desirable. It is surely as wrong to speak of a hernia "of the pleura" into the neck as it would be to speak of a hernia of the "peritoneum"—indeed more so; for in the former instance the pleura extends normally into the base of the neck beyond the chest walls. It is not easy to imagine a ruptured urethra in which there is no bleeding from the orifice, and we find no information as to the treatment of the traumatic stricture which results from such a rupture—one of the most difficult of all diseases to treat satisfactorily in a boy. We cannot agree with the statement that new growths on the tongue are as common in children as they are in adults. There are some other statements to which we take exception, but considering the general excellence of the book we must regard them as due to want of sufficiently careful proof-reading and not as the author's deliberate opinions. The type is clear and the illustrations (with the exception of Fig. 15) are good and adequate; the index is full, and the references are valuable.

Lehrbuch der Physiologischen Chemie. Von OLOF HAMMARSTEN, o ö Professor der Medizinischen und Physiologischen Chemie an der Universität Upsala. Dritte völlig umgearbeitete Auflage. Mit einer Spektraltafel. Wiesbaden: Verlag von J. F. Bergmann. (*Manual of Physiological Chemistry.* By OLOF HAMMARSTEN, Professor of Medical and Physiological Chemistry at the University of Upsala. Third Edition, entirely revised. With a Spectrum Plate. Wiesbaden: J. F. Bergmann.) 1895.

THOSE engaged in working at physiological and pathological chemistry, and especially those who have worked with the second edition of Olof Hammarsten's "Lehrbuch der Physiologischen Chemie," will welcome his third revised and enlarged edition of this work. In certain points it resembles Halliburton's work on the same subject, especially in so far as it is at once recognised that it can only have come from the pen of a man who is constantly engaged in the investigations of which it treats, and who is at the same time thoroughly well read in the literature of the subject. The natural overlapping of physiological and pathological chemistry, and the importance of a careful application of modern chemical knowledge and

Digitized by Google

methods to pathological processes, are well brought out. The revision of this edition of the book has in many cases been a re-writing of parts of chapters; the chapter on the Carbohydrates which has been added will at the present time excite special interest. Chapters on Proteids and Fats and a separate one on the Chemistry of Respiration are also valuable additions to Professor Hammarsten's work. As already mentioned, the literature of the various subjects treated is very complete, not only in regard to the references that are given, but also to those that are omitted; for in this part of the work the greatest discrimination has been exercised, and much valuable time will be saved to those who cannot afford to read every little paper that has been written if the investigator will follow Professor Hammarsten's lead. In a supplement of some twenty-four pages a short *résumé* of the literature that appeared after the actual chapters had been written and sent to press, but before the book was published, is given; this is a good plan and might well be widely imitated. It may be added that this, unlike many other German works of reference, is provided with a capital index.

A Manual of Obstetrics. By A. F. A. KING, A.M., M.D., Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Columbian University, Washington, &c. Sixth Edition, with 221 Illustrations. London: Henry Kimpton. 1896.

THIS book has been written with the purpose of presenting in an easily intelligible form such an outline of the rudiments and essentials of obstetric science as may constitute a good groundwork for the student beginning his obstetric studies. It is confessedly a compilation, and the author expressly acknowledges his indebtedness to several of the larger treatises. He also expects that it may be useful as a work of reference to the practitioner who has little time to look for what he requires in larger works. The publication of the sixth edition is sufficient evidence that the author's intention and expectation in these respects have been amply fulfilled. Several new illustrations have been added to the present edition, and the book has been thoroughly brought up to date.

A feature in which the book differs from several of the works on midwifery in common use in England is in possessing a chapter on the Jurisprudence of Midwifery, in which many of the medico-legal questions with which the practitioner may have to deal are treated in a more or less concise form. We notice also that in the chapter on the Resuscitation of Asphyxiated New-born Children there is a particularly lucid description of Schultze's method of artificial respiration, illustrated by an instructive diagram. It is not by any means every diagram intended to illustrate this method that is easily intelligible to students.

LIBRARY TABLE.

Ueber Episcleritis Periodica Fugax. Von Professor Dr. ERNST FUCHS in Wien. Pp. 45.—This pamphlet, which appears to be an extract from von Graefe's *Archiv für Ophthalmologie*, Band XLI., p. 4, gives an account of a recurrent inflammation affecting the conjunctiva and sub-conjunctival tissue, but which is not attended with any considerable exudation and is of a very transitory nature. Dr. Fuchs gave a sketch of the affection in a short paper he read before the Ophthalmological Section of the British Medical Association last year. In the present paper he gives a fuller account of it and supplies the details of various illustrative cases. The disease differs from ordinary episcleritis in its recurrent and fugacious character and in its occasionally affecting the iris and ciliary zone; it differs, moreover, in leaving no traces behind it and in attacking both eyes either simultaneously or successively. The inflammation is accompanied with pain, lacrymation, and photophobia. The duration of the attack is usually not more than two or three days. The treatment recommended by the author is an appropriate regimen, quinine and salicylate of soda.

Philip's Handy-Volume Atlas of London. London: Geo. Philip and Son. 1896. Cloth, post free, 4*s.* 2*d.*—For a person to find his way about this vast metropolis is becoming a matter of increasing difficulty, and yet to carry about and unfold a large map is tedious and inconvenient. This little book, of a size to go in the pocket, obviates this difficulty. Each sectional map, of scale three inches to the mile, occupies one opening, and an index at the end gives the appropriate reference. It is accurate and convenient, and to the busy practitioner, whether in family or consulting practice, it will be a saving of much time and annoyance. It also contains a list of cab fares and some useful general information.

Ueber Blepharochalasis. Von Professor Dr. ERNST FUCHS. Sep. Abdruck aus der *Wiener Klinische Wochenschrift*, No. 7, 1896. (*On Blepharochalasis.* By Professor E. FUCHS. Reprinted from the *Wiener Klinische Wochenschrift*, No. 7, 1896.) Pp. 5.—The affection described in this pamphlet is a condition of relaxation of the skin of the eyelids causing drooping, but differing from ptosis in the absence of muscular paralysis. It occurs both in young and in old people and in both sexes. The author considers it to consist essentially in an atrophy of the skin and subcutaneous tissue of the lids with thinning and loss of elasticity. He recommends the removal of a horizontal strip of skin from the lid, combined with Hotz's operative procedure.

Ueber zwei der Retinitis Pigmentosa verwandte Krankheiten. (On two Allied Forms of Retinitis Pigmentosa.) Von Professor Dr. ERNST FUCHS in Wien. Pp. 6.—In this pamphlet the author describes under the terms retinitis punctata albescens and atrophia gyrata choroideæ et retinæ forms of retinal degeneration which are associated with myopia and are accompanied by the formation of rounded white spots of retinal and choroidal atrophy which, commencing separately, fuse with one another, forming extensive white areas with convex borders. It is often hereditary.

NOTES FROM SOUTHAMPTON.—The Mayor of Southampton (Mr. M. Emanuel) on April 20th laid a foundation-stone in connexion with the further development of the sanitary works of Southampton rendered necessary by the enlargement of the borough. The full scheme will treat 1,350,000 gallons of sewage in dry weather, or 3,000,000 gallons including storm water. Tanks receive the sewage for treatment at a level to allow the discharge of the effluent on the ebb tides. The refuse destroyer has been enlarged and will, it is arranged, provide the necessary power to lift the sewage to the tanks mentioned. The sludge from the tanks will be conveyed thence by a sealed main and discharged into sealed reservoirs, where it will be chemically treated and allowed to precipitate a second time. Then the sludge will be pressed into large cakes and sold to agriculturists if possible; if not it will be destroyed by fire with the house refuse. At the same time the sewerage system will be improved and extended, and the whole cost is put at £40,000. At the last meeting of the Southampton County Council the medical officer (Mr. A. W. Harris) reported the occurrence of five cases of small-pox. The infection of the first was still a mystery; the second occurred thirteen days later, the patient being a lodger in the same house; the third was that of the inspector of nuisances who was engaged in the removal of the first case; the fourth occurred in a lad living next door to case No. 1; and the fifth was imported on board the troopship *Dilwara*. It was remarked by Mr. Eliot that the period of incubation had passed since the last case without a further recurrence. A very virulent case was brought to the port but was not landed, being taken directly to the hospital ship, where all five patients are removed.

Analytical Records
FROM
THE LANCET LABORATORY.

MEDICATED SOAPS.
(YARDLEY AND CO., LIMITED, RIDGMOUNT-STREET, E.C.)

APART from their medicated character these soaps present a well-balanced composition, so that the soap basis itself is not injurious to the skin. They are, in fact, superfatted and accordingly quite free from any excess of alkali. We have received and examined two specimens, the first consisting of superfatted ichthyol soap containing 5 per cent. of the ichthyol ammonium compound, and the second of superfatted soap containing 3 per cent. ammonium ichthyolate and 2 per cent. Peruvian balsam with sapo mollis B.P. Besides these Messrs. Yardley and Co. prepare the following: superfatted benzoin soap; superfatted ichthyol and tar soap; superfatted camphor, sulphur, and Peruvian balsam soap; salicylic sulphur soap; and hygienic soap. The formula of each and all is admirably adjusted to the specific requirements for which they are individually prepared. In various skin complaints the use of such soaps, and especially those containing ichthyol, is of well-known value.

INVALID CONSOMMÉ.
(G. VAN ABBOTT AND SONS, 6, DUKE-STREET MANSIONS, GROSVENOR-SQUARE, W.)

Preparations of this class though of a moderate degree of nourishing power are of distinct value to the invalid because they are easily digested besides being palatable and attractive. The degree of nourishing power is of course moderate in a preparation containing 3·70 per cent. total solid matter; but it makes an excellent *consommé*. It is a clear amber-coloured jelly liquefying readily on warming. Analysis gave the following results: water, 96·30 per cent.; organic matters, 2·49 per cent.; and mineral matters, 1·21 per cent. The organic matter contained albumin, 0·07 per cent.; peptones, &c, 1·08 per cent.; and crystalline principles, 1·34 per cent. It is a preparation which the invalid will be grateful to have included in his dietary.

"ORION" SOUTH AUSTRALIAN WINES.
(E. BURNEY YOUNG, SOUTH AUSTRALIAN GOVERNMENT BONDED DEPÔT, OFFICES, 35, WALBROOK, E.C.)

The steady increase in the importation of light, pure wines from our "big colony" into this country is distinct evidence of their growing popularity and of a healthier demand in the direction of alcoholic beverages. Australia is at a moderate cost sending us really good wines of the excellent type of those before us, and each year sees a marked improvement in the tone and quality of the vintage. The following analyses of three samples of the "Orion" brand, which have the unquestionable advantage of being certified as pure and sound by the experts of the South Australian Government, illustrate the composition of these wines and serve to bring out their really excellent qualities. Cabernet: alcohol, by weight 11·69 per cent., by volume 14·46 per cent., equal to proof spirit, 25·34 per cent.; extractives, 2·27 per cent.; mineral matter, 0 28 per cent., containing 0·8 per cent. oxide of iron; fixed acid, reckoned as tartaric acid, 0·4 per cent.; volatile acid, taken to be acetic acid, 0·039 per cent.; and glucose, 0·14 per cent. This wine was in excellent condition and, as will be seen, is free from excessive acidity, contains a minimum of sugary constituents, possesses body, while it exhibits an acceptable and characteristic flavour. Burgundy: alcohol, 13 54 per cent. by weight, 16·70 per cent. by volume, equal to 29·27 per cent. proof spirit; extractives, 2·63 per cent.; mineral matter, 0·25 per cent., containing 0·8 per cent. oxide of iron; fixed acid (tartaric acid), 0·38 per cent.; volatile acid (acetic acid), 0·10 per cent.; and sugar, 0·16 per cent. This wine is of a rich Burgundy character, containing somewhat more extractives than the last, but still only trifling quantities of volatile acid and sugary constituents. It is a sound and pure product and well adapted as an invigorant and tonic. Riesling: alcohol, by weight 11·77 per cent., by volume 14·56 per cent., equal to 25·51 per cent. proof spirit; extractives, 2·34 per cent.; mineral matter, 0·19 per cent., containing 1 per cent. oxide of iron; fixed acid (tartaric acid), 0·33 per cent.; volatile acid (acetic acid), 0·011 per cent.; and sugar, 0·20 per cent. This is an agreeable light white wine of the well-known Riesling stock; it is "clean" and pleasant to the palate. Its alcoholic strength is practically the same as the Cabernet wine; the volatile acidity is practically *nil*, and the amount of sugar is very small; its genuineness cannot be doubted. The wines one and all were found to be quite free from added and objectionable preservatives. Taking these results as a whole we may remark that they are entirely in accordance with the guarantee that these wines are pure and sound.

LEVICO (ARSENIO-FERRUGINOUS) WATER.
(HERTZ AND COLLINGWOOD, 38, LEADENHALL-STREET, E.C.)

Levico Water has recently come to the front as being of peculiar value chiefly in the treatment of chlorosis, anæmia, and in syphilitic conditions. It is mentioned very favourably in the clinical records of many physicians on the Continent. The water is derived at an altitude of nearly 5000 ft. above sea level on a branch of the Monto-Fronte Hills about twelve and a half miles distant from Trient, in the Southern Tyrol. The springs from which the water is drawn occur at Levico, a small health resort situated at the foot of the hills. There are two perfectly distinct springs, the one yielding a water rich in both ferruginous and arsenical constituents, and the other a water of a weaker arsenical and ferruginous composition. We have recently examined both waters, which may be procured in this country in bottles. They both contain iron, chiefly in the ferrous state, in large excess, a traceable amount also of copper, and a distinct quantity of arsenic. The strong water contains the equivalent of about one-twelfth of a grain of arsenious acid per pint, along with thirty-four grains of iron salt; and the mild water contains just a tenth of the quantity of arsenic per pint, with eight grains of iron salt. These constituents probably have their origin in the fact of the water flowing through a bed of iron pyrites, containing, as it usually does, a noteworthy proportion of arsenic. It will be seen that the quantity of arsenic is small, but, as is well known, arsenic is most effectual in conditions of anæmia when administered continually in small doses. It is associated in Levico Water with iron, the assimilation of which in acting as a powerful tonic is calculated to be assisted by the favourable action of arsenic on the nervous system. The therapeutic value of the Levico Water in various conditions of disease and weakness is spoken of so highly on the Continent, and its administration appears to be attended with such benefit, that practitioners at home may find it worth while to give this interesting natural water a trial.

(1) VARIOUS PALATINOIDS; AND (2) SCULCOPINE.
(OPPENHEIMER, SON, AND CO., LIMITED, 14, WORSHIP-STREET, E.C.)

We have received from this firm specimens of bi-palatinoids of ferri hypophos. co., in which the value of this particular form of administering drugs which together are unstable is clearly demonstrated. Thus the tendency of the strychnine to deposit in the ordinary syrup is obviated, and the risk of the patient taking the last dose with a dangerous amount of deposited alkaloid in it is avoided. Since the contents of the bi-palatinoid are not tasted there is no necessity for the use of syrup, which in some cases may give rise to objection. In addition, accuracy of dosage is secured and the

Digitized by Google

bi-palatinoid is easily taken. Of undoubted convenience and value, also, are the palatinoids containing chlorodyne (1 minim) and the palatinoid containing pure creosote (½ minim). The creosote in the latter is of a specially refined kind, and by this means of administration the unpleasant and persistent effects of the drug in the mouth are avoided. Sculcopine is described as an alcoholic distilled extract of fresh hydrastis canadensis, containing all the active principles of the drug, which are of value in the treatment of hæmorrhages and inflammatory and irritating surfaces. It is a clear, yellowish liquid, with persistent bitter taste. With perchloride of iron it gives practically no reaction indicative of tannic acid. It is said to be a valuable hæmostatic in uterine hæmorrhages and a tonic and sedative, and is of peculiar value in inflammatory and irritable conditions of the mucous surfaces.

New Inventions.

AN ARTIFICIAL NOSE AFFIXED WITHOUT SPECTACLES.

SOME months ago I published a case in which a woman whose nose had been destroyed by lupus had had the missing parts artificially replaced by a vulcanite nose held in place by spectacles. Since publishing this case I have made several noses and have discovered many improvements in the method of adjustment which seem to me worth recording. In those cases where spectacles are necessary the main difficulty to be overcome is the line of shadow at the sides where the painted nose ends. This I have greatly modified by means of tinted wool prepared for me with great patience and ingenuity by Mr. Martindale of New Cavendish-street. The spectacles themselves have been rendered much firmer

by a special shank to go round the ear, which Mr. Hawes has contrived. The colour and texture have also been rendered more life-like by the use of coloured powders of varying tints also prepared for me by Mr. Martindale. Lastly I have in two cases dispensed with glasses altogether, and attached the nose with spirit gum. The accompanying illustration is of one of these cases, which was shown at a recent meeting of the Odontological Society. The great difficulty is the modelling. If the new nose is not in keeping with the rest of the face no ingenuity can disguise its nature; if, on the other hand, it is the right type and properly modelled its colour may be far from right and still it will not attract attention.

ARTHUR S. UNDERWOOD,
Professor of Dental Surgery, King's College.

Wimpole-street, W.

AN ASEPTIC CATHETER.

THE complete asepticity of catheters being of great consequence in the interest of the patients, any means by which its attainment is facilitated tends to lighten the work of the surgeon. With this end in view I have devised a catheter which is not tubular but consists simply of a grooved

staff with a solid beak. I think that it will in many cases be found convenient by country practitioners and by patients although the principle cannot be applied to small-sized catheters such as would be used in very tight strictures. It has been made for me by Messrs. Gardner and Son of Edinburgh and Glasgow.

R. W. FELKIN, M.D.

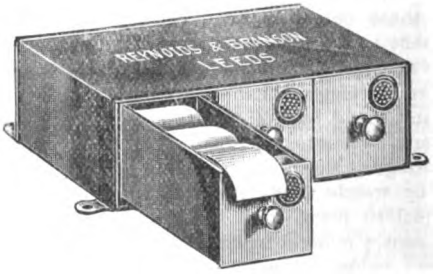
Alva-street, Edinburgh.

THE "VENTAIR" CAP.

THERE is room for a good deal of improvement from a hygienic point of view in the construction of hats and caps. The chief difficulty consists in making a cap which shall be waterproof and protective to the head and yet which shall admit of ventilation without danger of chill. In fact, the difficulty is to avoid the two extremes of, on the one hand, too free draught, and, on the other, of no ventilation at all. The "Ventair" cap aims with some distinct success, we think, at producing a comfortable and at the same time a hygienic covering for the head. The cloth or material from which the caps are made is so woven as to leave open-work spaces which may be seen through, but which do not permit water, odd as it may appear, to penetrate the material. At the same time ventilation freely and uniformly takes place. We have exposed a cap to a heavy shower of rain with the result that though the external surface was freely wetted there was no sign of wet inside, and on briskly shaking the cap most of the water on the outside could be removed. For cyclists, sportsmen, and others it should supply a much felt want. The makers are Messrs. Ingle and Co. of 20, Cheapside, E.C.

PATENT DUSTPROOF SELF-CLOSING DRAWERS.

MESSRS. REYNOLDS AND BRANSON, surgical instrument makers, &c., of 13, Briggate, Leeds, have taken advantage of the fact that dust is sucked into drawers and boxes with a fall in the temperature of the air by making a drawer with all its parts tight-fitting except a portion in front called an air filter, loosely packed with a suitable filtering medium. The result of this is that the air, taking the easiest passage, on contracting or expanding passes through the filter, leaving



the dust it contained in the filtering medium, which on becoming dust-laden can be easily renewed and that practically without cost. For the storage of surgical dressings and such-like things the invention should be valuable. The specimen which is before us is neat in appearance, being made of drab-enamelled tin. By means of a spring the drawer is made self-closing, but remains open when pulled out to the maximum by slightly depressing it. The illustration shows a nest of three drawers, but they are made in all sizes with as many compartments as may be desired. The price of a single drawer is 7*s.* 6*d.*, set of four £1 5*s.*, and set of eight £2 2*s.*

THE LANCET.

LONDON: SATURDAY, MAY 2, 1896.

"THE Battle of the Clubs," as related by our Special Commissioner with a fulness of detail never before realised, cannot leave the profession where it found it. If such revelations do not lead to a better state of things they must lead to something even worse, if that can be. They have been effective at least in this respect: that they have placed the whole system before the profession. Possibly many of the facts that have been elicited and so clearly exposed by our Commissioner are known to the General Medical Council or to the committee appointed by that body for the special investigation of this subject. But whatever may have been the evidence taken by that committee it was never published. It seemed to convince the Council that there was much that required the attention, perhaps the condemnation, of the profession, acting through its corporations or its voluntary associations. But it was given in confidence and was not of much practical utility. It is altogether otherwise with the remarkable communications of our Special Commissioner. They are based on personal visits to places as different as Brussels from Birmingham, or Portsmouth from Leicester, or Lincoln from Walsall. They embrace every kind of club, from those conducted by laymen to those exploited by one or other of the great friendly societies, or by an amalgamation of these into a huge overgrown medical aid association, or the venture of a commercial company carrying on the double business of life assurance and medical attendance. He has seen all persons concerned in such ventures. He has listened to every side of the question and given a fair hearing to apologists. These communications have been going on now for a great part of a year and they have been practically uncontradicted. There has been no serious answer to the main charges, which are repeated with painful monotony in the account of every successive place visited—viz., that the medical club system has become a huge tyranny all over the country, interfering rudely with the old system of private practice, or private club practice under which there was a lasting and friendly relation between a given medical man and the people whom he attended, and establishing in its place a monster system of wholesale medical attendance where patients are seen some times at the rate of sixty an hour—and in epidemic times even yet more rapidly—and for which the medical man receives remuneration at the rate of 3*d*. or 4*d*. a visit. This would be bad enough if it was applied only to the poorer section of the working classes, but it is applied to the wealthier section—to well-paid artisans and mechanics and foremen. Nor does it stop there even. The intolerable feature of the system is that it is applied unblushingly to all classes—to tradesmen, very extensively to publicans, even to wealthy employers of labour residing in comfortable villas two or three miles out of town who expect the medical man to leave the poorer members and to attend to them for the pittance of 4*d*. a visit. Ex-mayors, aldermen, and councillors—gentlemen who would be ashamed to draw sick allowance from the funds of the lodges of which they are members—are not ashamed to take the medical man's services at 3*s*. 6*d*. a year, of which he perhaps gets a third, though they can command a consultant from a neighbouring town and pay him 10 or 20 guineas. These are the remarkable facts which remain in uncontradicted evidence in our pages and which have brought things to a sharp pass between the medical profession of England and the working classes.

The crisis is so acute that at the recent conference of the Friendly Societies' Medical Alliance held in Wednesbury on April 16th, the meeting, according to the *Nottingham Daily Guardian*, was mainly occupied with the strained relations between the medical profession and the various affiliated associations. Well might the conference be so occupied. When the friendly societies of England estrange the medical profession they injure themselves, yet if all evidence is not false they are sweating medical men on a wholesale scale and they are using their organisations to destroy the private practice of medicine. We expect better things of the working classes. They are getting rapidly richer, and their first duty to a profession which has always treated them well is to use some of their accumulating savings in remunerating medical service and to help the profession in its firm determination to refuse medical attendance on club terms to men who are no longer poor enough to need such accommodation. The profession has no wish to interfere with the right of the friendly societies to admit whom they please to their membership, but it has a most decided right, and it is determined to act upon it, to refuse to allow these societies to impose on its members the duties of attending rich men on terms only tolerable in the case of those who are not rich. These societies go beyond their function altogether when they claim to destroy medical practice and, by a side wind, to degrade its conditions. One of the measures resolved on at the conference seems to show that the Friendly Societies' Medical Alliance is very unfit to advise its constituents as to the best means of restoring the harmony between the societies and the profession. Our readers will scarcely believe that it was actually proposed to ask Parliament to grant medical diplomas to medical students to act as medical officers to the associations. We grant that the terms of the association are only fit for students and not for qualified practitioners. But Parliament is not likely to allow HER MAJESTY'S subjects to be experimented on by students even to please the friendly societies.

The only other practical outcome of the conference seems to have been a determination to appeal to the General Medical Council. It is noticeable that the Medical Defence Union has undertaken, if well-proved cases of touting can be supplied to them, to bring them under the notice of the General Medical Council. This shows that the appeal to the General Medical Council may not be the one-sided thing contemplated by the conference. In the end Mr. Alderman DICKINSON of Lincoln and Mr. WILLIMENT of Norwich were appointed to seek an interview with the General Medical Council. Whether the Council, on such an appeal, will adhere to the view that such questions are not for its decision we cannot say. There

Digitized by Google

is more to be said for the Council's interference here than has yet been said. Be this as it may, the profession is roused as it has never been before to perceive the pits into which it is being dragged, and, apart from its ethical Authorities, is showing a determination to defend itself which cannot be too much praised. We are pleased to think that our Special Commissioner has contributed such valuable material for a fair public and professional opinion on this subject.

RECENT events have served to attract a large amount of attention to the racial and political problems of South Africa. It may not be inopportune if we take occasion to point out some of the leading features of that country from the health point of view and its attractions for the immigrant who is compelled by personal considerations to take account of climate in his selection of his future home. There is no doubt that South Africa is in these regards a favoured region and that it affords many suitable resorts for invalids, especially the sufferer from pulmonary affections, and also numerous districts where the British race can attain a high level of vigour and fertility. Many of the pests of Europe and the western world—e.g., hydrophobia, yellow fever, &c.—are here unknown, and the general climatic conditions are highly favourable to an out-door life of healthful activity. Malaria, which is such a curse to the littoral regions of Western and Eastern Africa, is much less prevalent in the southern portions of the great continent and in a large part of the interior is practically unknown. It is a most fortunate circumstance that so much of the interior of South Africa is an elevated plateau, as the elevation serves most materially to mitigate the heat which otherwise would render the country as unsuitable for extensive European settlement as the great plains of India.

The configuration of South Africa has been compared to an irregular flight of four steps, the first consisting of the coast plateau, with an elevation of about 600 feet; the second of the southern karoo, elevation about 1200 feet; the third of the central karoo, elevation about 2500 feet; and the fourth of the northern karoo, elevation 4000 feet and upwards. The climatic characters of these four regions necessarily present considerable diversity. The coast plateau is on the whole warm and moist. The rainfall on Table Mountain ranges from fifty-four to seventy-eight inches per annum, and the average for the whole Cape Peninsula is forty inches. Rain falls chiefly in the winter months, from April to September, the three hottest months—viz., January, February, and March — being almost rainless at Cape Town. On the east coast, however — at Durban, for example, — most rain falls in summer, and this is also the rule in the interior, where the winters are usually dry and clear, with slight frost in some localities. None of the places on the coast plateau enjoy a very high repute as health resorts, and as a broad rule the invalid—especially the *poitrinaire* — should be advised to avoid the coast and seek some of the elevated localities of the interior. The southern karoo presents a decided contrast to the coast plateau. The climate here is on the whole dry, with considerable oscillations of temperature and a greater contrast of season. The well-known health resort Ceres, distant about fifty-five miles from the coast and at an elevation of 1493 feet, may be taken as a good example of the climate of the southern karoo. The mean maximum temperature ranges from 58° F. in July to 85° in February, and the mean minimum temperature from 34° in July to 55° in January. The mean relative humidity is 75. The rainfall, though large—viz., forty-one inches—is chiefly confined to the winter months, and the total number of wet days in the year — viz., sixty-eight — is small. The central or great karoo extends east and west for a distance of about 350 miles, at an elevation of from 2000 to 3000 feet above the sea. Here we are in the region of drought, the rainfall varying from about ten inches in the west to eighteen in the east, and in summer these vast plains present a desolate appearance. The hottest month is January, with a mean maximum of 87°, and the coolest is July, with a mean minimum of 36°. The winters are bright and clear, with cold nights, and snow sometimes lies for a time upon the mountains. The air is very pure and dry, and although dust-storms are not infrequent the atmosphere is comparatively still, especially in winter. Among the best-known resorts in this region are Beaufort West and Matjesfontein. The northern karoo—of which the elevation varies from 2800 to 6000 feet—stretches to the Orange River and has an extremely dry climate, the rainfall in some parts being as low as two inches and the general average being about ten inches. Thunderstorms are frequent in summer, the extremes of temperature are considerable, and in winter severe frosts are not unknown. On the whole the winter climate is very agreeable; bright, clear, sunny, bracing days, with just a touch of frost in the air, being very frequent. The chief resorts on the northern karoo are Cradock, Queenstown, Tarkastad, and Aliwal North. The Transvaal, about which so much has recently been heard, is an elevated plateau with a very healthy climate; Pretoria is at an elevation of 4500 feet above sea-level; and Johannesburg is at an elevation of 5600 feet. In spite of this elevation the summer heat in these places is very great and dust-storms are frequent. Malaria is common in some parts of the Transvaal during the hot rainy season; nevertheless, the climate in general must be pronounced healthy and favourable to Europeans. It is probably less favourable for pulmonary cases than the districts already mentioned in Cape Colony.

The practical deductions from the above facts are not difficult to draw. South Africa is one of the best regions in the world for suitable cases of incipient or chronic stationary phthisis, but much care is necessary in the choice of locality. The fairly vigorous patient will there find a climate presenting an unusually large proportion of dry, sunny, bracing days and ample facilities for out-door exercise and sport. The drawbacks to the country are the inadequate accommodation — especially as regards hotels and sanatoria,—the monotony of diet, and the temptations to *ennui*. Railway facilities are being rapidly developed, and the country is being opened up in a way that promises to make it in the future much more tempting to the traveller for health than it has been in the past. Still, South Africa must for the present be recommended only to the robuster type of patients, especially to those accustomed to travel and not averse to roughing it when necessary. The cases most likely to be benefited are incipient or chronic stationary

Digitized by Google

phthisis, impaired convalescence after operation or acute disease, "struma," anæmia, rheumatism, some varieties of dyspepsia, some varieties of bronchitis and asthma, and Bright's disease. Dr. LAING GORDON'S paper in THE LANCET of Feb. 29th contains some useful information and confirms the favourable reports of other observers regarding the value of the South African highlands in the treatment of phthisis.

MR. LECKY'S recent work on "Democracy and Liberty" exhibits all the great qualities which have characterised his other contributions to our literature. Extensive scholarship, wide sympathies, philosophic breadth, great charm of style, courage, and candour,—these are the historian's well-known characteristics, and they have rarely, if ever, been more evident than in the work in question. Its subject matter is, however, to a large degree eminently controversial, and no doubt the writer's line of thought and argument will provoke much comment and not a little dissent. The political side of the many important questions dealt with by Mr. LECKY lies outside our province, but we may fairly draw the attention of our readers to the noble tribute paid in more than one passage to the great benefits conferred during the present century on humanity by the workers in the field of sanitary reform and pathological research. "The great work of sanitary reform," says Mr. LECKY, "has been perhaps the noblest achievement of our age, and, if measured by the suffering it has diminished, has probably done far more for the real happiness of mankind than all the many questions which make and unmake Ministries." Workers in this field of endeavour have often reason to complain that their work is done in secret, and that though it shows its fruits in a reduction of mortality, an increase of the average length of life, of the working power of the community, and of the general sum of human happiness, it wins but small recognition and is too often taken simply for granted. It is no small satisfaction to find perhaps the greatest of our historians fully alive to the great part played by sanitary reformers in the general progress of the age. "Among the many addresses that were presented to the QUEEN in her jubilee year," continues Mr. LECKY, "none appeared to me so significant as that which was presented by the sanitary inspectors, summing up what had been done in England during the first fifty years of the reign. They observed that the general health of HER MAJESTY'S subjects had advanced far beyond that of any great state of Europe or of the United States; that the mean duration of life of all the QUEEN'S subjects had been augmented by three and a half years; that in the last year's population of England and Wales there had been a saving of 84,000 cases of death and more than 1,700,000 cases of sickness over the average rates of death and sickness at the beginning of the reign; that the death-rate of the home army had been reduced by more than half and the death-rate of the Indian army by more than four-fifths." It is extremely satisfactory to have these facts put so prominently forward and to have such an ungrudging tribute paid from such a source. Mr. LECKY has no sympathy with those sentimental faddists who think that in these days of triumphant democracy no compulsion should be used to secure the general adoption of hygienic precautions. "The real justification of the law imposing compulsory vaccination on an unwilling subject," he justly remarks, "is not that it may save his life, but that it may prevent him from being a centre of contagion to his neighbours. In all legislation about drainage, pollution of rivers, insanitary dwellings, the prevention of infection, and the establishment of healthy conditions of labour, spasmodic and individual efforts, unsupported by law, will always prove insufficient. As population increases and is more and mor massed in large towns; as the competition for working men houses within a limited area grows more intense; as industry takes forms which bring great numbers of working men and women under the same roof; and as multiplying schools increase the danger of children's epidemics, the need for coercive measures of sanitary regulation becomes more imperious." These principles are to the members of the medical profession simply self-evident, and it would save an immense waste of time, labour, writing, and talking if they were universally attended to and if ignorant people would refrain from giving vent to crude opinions regarding subjects which they have never seriously attempted to master.

Mr. LECKY is no less generous when he comes to comment upon the singularly modest rewards which have been bestowed upon the most distinguished representatives of medical science and sanitary reform. We trust the following noble and eloquent passage will be duly pondered "by all whom it may concern." We could not wish to have our case more forcibly or more adequately stated. "Closely akin to science, and perhaps even more important among the elements of national well-being, are the great healing professions. Here, too, our century ranks among the most illustrious in the history of the world. It has seen the discovery of anæsthetics, which is one of the greatest boons which have ever been bestowed upon suffering humanity. It has produced the germ theory of disease, the antiseptic treatment in surgery, a method of removing ovarian tumours which has successfully combated one of the most terrible and most deadly of diseases, a method of brain surgery which has already achieved much, and which promises inestimable progress in the future. It has vastly extended our knowledge of disease by the invention of the stethoscope, the clinical thermometer, the laryngoscope, the ophthalmoscope, and in many other ways which it is not here necessary to enumerate England may justly claim a foremost place in this noble work, and many of her finest intellects have been enlisted in its service. In no single instance has this kind of eminence been recognised by a peerage. It is clearly understood that another and lower dignity is the stamp of honour which the State accords to the very highest eminence in medicine and surgery, as if to show in the clearest light how inferior in its eyes are the professions which do most to mitigate the great sum of human agony to the professions which talk and quarrel and kill." We conclude by quoting the following closely adjacent passage, the weighty words contained in which need no comment from us: "In 1896 for the first time a peerage was conferred on an English artist. The doors of the Upper House were never opened to the men who in this century have rendered the greatest services to the State and to humanity—to SIMPSON, whose discovery of chloroform has prevented an amount

Digitized by Google

of human suffering which it would need the imagination of a DANTE to realise; to STEPHENSON, whose engineering genius has done more than that of any other man to revolutionise the whole economical and industrial condition of England; to CHADWICK, the father of the great movement of sanitary reform which has already saved more lives than any, except perhaps the very greatest, conquerors have destroyed; to DARWIN, who has transformed our conceptions of the universe and whose influence is felt to the farthest frontiers of speculative thought. For their own sakes it is not to be regretted that the claims of such men were not thrown into humiliating competition with those of the acute lawyers and politicians, the great country gentlemen and the opulent brewers, who throng the approaches of the Upper House; but if such a House is to continue, and in a democratic age is to retain its weight and influence in the State, it is not likely that elements of this kind can for ever be neglected."

Annotations.

"Ne quid nimis."

THE SECOND READING OF THE MIDWIVES BILL.

THOSE who deprecate haste in dealing with the various Bills for saving the lives of puerperal women attended by ignorant and incompetent women calling themselves midwives may be reassured. Mr. Balfour has given pretty plain notice that even Wednesdays are not to be free for the discussion of Bills brought in by private Members. Even apart from this circumstance, and although the subject has been under the notice of Governments and of the General Medical Council for twenty years, there is much to be said for a year's delay. Of three or four proposals for dealing with this subject only one is before the House, and the Bill in question ignores most of the suggestions of the General Medical Council. Under these circumstances, while profoundly convinced of the need for some protection to poor lying-in women, we cannot but think that the Legislature will be well advised in waiting another year till the other measures with the same object are before the House and before the General Medical Council.

THE VACCINATED ANTI-VACCINATIONISTS OF GLOUCESTER.

FOR their own sakes, as well as for the sake of the community generally, we are glad to learn that many of the anti-vaccinationists of Gloucester are getting themselves vaccinated; but it is well to remember that were it not that these people had already been vaccinated in infancy there would probably be no anti-vaccinationists at all. The protection afforded by an original primary vaccination in infancy, though diminishing with advancing years, still affords some definite protection for a large majority of persons during non-epidemic periods; and hence it becomes very easy for the vaccinated anti-vaccinationists to decry vaccination when there is not much small-pox about and then to retire into comparative quietude and even get vaccinated when an epidemic phase of the disease sets in with intensity. At the present moment Gloucester exhibits two groups of anti-vaccinationists. One group—comprising people who are few and far between—is represented by the guardian and town councillor who recently stood up in a public meeting and announced that he had been in error, that he had become "converted" by what he had seen, and that he had been vaccinated in consequence. The other—and persons in this group are in the majority—includes those who have been vaccinated quietly and without any open confession of "conversion," some even seeking vaccination in distant places rather than make confession of their error. But Gloucester also exhibits a hybrid between these two in the person of the editor of the newspaper which has taken the lead in anti-vaccination articles. This editor has issued a public letter, which is extremely humorous, in which he announces that he has been "influentially urged" to get vaccinated, and hence he has sacrificed his "personal convictions" in the hope of contributing to "the public good." His vaccination is doubtless—as it nearly always is with anti-vaccinationists—a revaccination, and his public announcement is held by him "as sufficient excuse for my seeming inconsistency." We can assure him that he is in no way inconsistent in his humour. Like others of his class he is frightened of small-pox when it comes near him and he has submitted himself to inoculation by "the disease called by the name" vaccination, and now he can be pretty sure of retaining in redoubled force a protection which he doubtless had partially before. We have assumed that the editor is full of humour in his public letter, for we cannot for one moment assail the intellects of the people of Gloucester to whom his letter is addressed by thinking that they can possibly take him seriously.

COVERING IN THE LEGAL PROFESSION.

THE law is very severe against any solicitor who forms an alliance with an unqualified person in the way of partnership and for joint benefit. Such a case heard before the Queen's Bench Division will be found reported in the *Times* of Thursday, April 23rd last, headed "In *re* a Solicitor—*ex parte* the Incorporated Law Society." The solicitor was charged with a breach of the 32nd Section of the Solicitors Act, 1843. The motion was to strike the solicitors name off the rolls. Complaints were made by clients who employed the respondent as solicitor that the person who conducted the business was one Gillard. The respondent stated in defence before the committee of the Incorporated Law Society that the arrangement with Gillard was to pay him £2 10*s*., and that while he was kept at home by business Gillard had managed the common law branch of his business for him. Mr. Jelf, Q.C., in defending, also pleaded that even if there was partnership it did not matter unless the business was carried on for the sole benefit of the unqualified person. The committee which reported found no entry of the payments described, that the relationship between the respondent and Gillard was not that of principal and clerk but of partners, and that the offence against Section 32 of the Solicitors Act had been committed. Mr. Baron Pollock said it was most important that the client should know who was the responsible solicitor, and the Court made the order moved for and the solicitor's name was ordered to be struck off the Rolls.

MEDICAL DIAGNOSIS.

IT does not very often happen that we are able to present to our readers a communication by one whose medical experience includes recollections of more than fifty years' active work in the profession. It is therefore with pleasure that we publish to-day the address given to the North London Medical and Chirurgical Society by the retiring president. Mr. Charles King is to be envied in that he possesses not only the recollections of his first period of clerkship under Dr. Addison more than fifty years ago, but also the experience which he has been able to gain by taking recent advantage of the still great opportunities afforded by his old hospital as a school of medicine. We must admit, however,

Digitized by Google

to having experienced a slight feeling of disappointment in perusing Mr. King's admirable address. An experience which goes back to the time when all the apparatus required by his clinical clerk to convince Dr. Bright or Dr. Addison that a specimen of urine contained albumin was a "candle and a spoon," and which is also able to put before an audience the fact that a "Roentgen skiogram" is produced as evidence of injury to the foot in a court of law under the discriminating guidance of Mr. Justice Hawkins, must be of the most interesting character; and an account of that experience, when its possessor has the facility for entertaining description and narrative of the retiring President of the North London Society, would prove most instructive. The recent advance in "shadow photography" is not that, however, on which Mr. King laid the greatest stress when contrasting the days of his studentship and the present time from the point of view of accuracy in diagnosis. The diagnostic instrument which he makes most prominent among the rest is no doubt the microscope. Whether this instrument is considered as an aid to the surgical diagnosis of tumours, or from the point of view of the examination of obscure affections of the genito-urinary tract, or as a necessary adjunct to the numerous bacteriological examinations which are becoming more frequently practised every day, or as indispensable in a multitude of other diagnostic investigations, it is the microscope and clinical microscopy which have done most to make advance possible; and in this opinion all will agree with Mr. King.

CROSSED KNEE-JERK.

IN the *American Journal of the Medical Sciences* for March Dr. Risien Russell has an interesting paper on this subject. Some time ago Dr. Hinsdale and Dr. Madison Taylor offered an explanation of the occurrence of this phenomenon as a result of a centripetal impulse producing activity of one cortical motor area which in turn stimulates the corresponding portion of the other hemisphere and produces a contraction of the adductors of the thigh opposite to the one originally struck. Dr. Russell carried out certain experiments with the view of testing this hypothesis, using dogs and rabbits for the purpose. In the first set he divided the corpus callosum, but even after this procedure, when an active state of the knee-jerks was induced by a certain degree of asphyxia, it became possible to elicit beyond all question the crossed knee-jerk. Further, in order to test whether the cerebrum was concerned at all in the production of the crossed knee-jerk the spinal cord was completely divided transversely in the dorsal region. In the course of a week well-marked exaggeration of the knee-jerks ensued, and it was also possible to evoke, not only a crossed knee-jerk, but a greatly exaggerated cross-jerk. Another effect was sometimes observed—viz., that a blow on the distal end of the femur or proximal end of the tibia was followed by contraction of the opposite adductors of the thigh and extensors of the knee, while there was no response in the extensors of the side on which the blow was delivered. This phenomenon is not explained; the fact is merely recorded. Dr. Russell next traverses Dr. Hinsdale and Dr. Taylor's views of the nature of what has somewhat unfortunately been named reinforcement. These writers regard this phenomenon as resulting from irradiation of motor impulse from the active centres to other similar centres, so that they and their related muscles acquire a heightened responsiveness to external stimuli. Dr. Russell points out, however, that any voluntary motor impulse directed to the muscles on whose contraction the knee-jerk depends diminishes the possibility of eliciting the phenomenon. And he mentions that in using the Jendrassik method the extensors of the knee are sometimes brought into action, and this, instead of increasing the knee-jerk, renders it difficult or impossible to obtain. Dr. Russell believes with others that the spinal centres are normally under a certain degree of restraint by cerebral centres, and that what is called reinforcement is really removal in some degree of this inhibition, a removal which may be effected by diverting the patient's attention to some other act. Removal also of one hemisphere in an animal causes increased activity of the opposite knee-jerk. Further, the return of the knee-jerk in Kramer's case of progressive paresis, which was quoted by Dr. Hinsdale and Dr. Taylor in support of their views, Dr. Russell accounts for by supposing the inhibition lessened as a result of progressive cerebral degeneration, so that there comes a time when the spinal centres are so far freed from inhibition that the few remaining fibres in the posterior columns are sufficient for the purpose of carrying a stimulus which was formerly ineffective because of the inhibition from above, and as illustrating the same point he quotes a case published by Dr. Hughlings Jackson and Dr. James Taylor of a man suffering from tabes in whom the knee-jerks returned after an attack of hemiplegia.

THE SALE OF DISEASED MEAT.

A CONVICTION was successfully obtained last week against a dealer for selling meat which was wholly unfit for human food. In many cases of this kind there are various technicalities which often cause some difficulties in getting a conviction, but in this case the whole affair seems to have been so barefaced that there was, as Mr. Alderman Samuel remarked, practically no defence. The farmer to whom the cow had belonged stated that as the animal was unable to stand he sent for the defendant to take it away, receiving nothing for it as it was quite useless to him. The defence was that the meat appeared quite healthy when it was dressed, but Dr. Sedgwick Saunders thought its diseased condition must have been quite apparent, as when he examined it he found it saturated with tubercles, soft and unhealthy, so that its consumption would have been attended with immediate danger to life. Previous convictions having been proved against the accused he was sent to prison for three months without the option of a fine.

THE CEMETERY AND THE WATER-SUPPLY.

PETRIFYING springs, the waters of which are so highly charged with lime salts or silicates as to infiltrate and encrust objects suspended therein for some time, are known in most countries, but their relation to the question of earth burial has, we believe, never presented itself until this year. We learn, however, from a German paper that excavations made with the view of ascertaining whether a portion of the churchyard at Löbau laid out in 1870 was ready for renewed interments revealed the fact that the coffins were intact and completely petrified. On being broken open they were found to be full of water and the corpses were sodden but hardened, though they had undergone a certain amount of putrefaction, pungent gases escaping as the coffins were opened. The surface soil was a heavy, impervious clay, beneath which was a water-bearing zone in which the bodies lay. In this instance the water affected them, but had it been of an ordinary character they might have dangerously affected it, the exclusion of air and the absence from the "dead" clay of the bacteria of nitrification having prevented any decomposition in the strict sense as distinguished from putrefaction. Thus, when part of the churchyard of St. Andrew's, Holborn, was excavated for the construction of the viaduct the bodies were found "sandwiched," to use the apt expression of Dr. S. Gibbon, the medical officer of health, between the boards of the coffins,

Digitized by Google

crushed by the superincumbent weight of clay; but from the "deadness" of wood and clay decomposition and disintegration had been very slow, and there was but little difference between the state of preservation of those interred 200 years ago and of those buried twenty years previously, when the graveyard was closed. Under such circumstances—that is, in non-nitrifying and therefore unsuitable soils — the pollution of the ground-water is inevitable, and though the danger to the public health is minimised by the provision of public water-supplies from distant sources it is a serious matter when the population depends on private wells. Thus at Vienna, previously to the inauguration of a public supply from the highlands, the effects of the pollution of the ground-water gravitating from the cemeteries encircling the city on higher elevations were unmistakable. The water in the town wells became progressively more and more contaminated until it was turbid, yellow, charged with nitrites, and finally redolent of sulphuretted hydrogen and ammonium sulphide—in fact, absolutely unfit for any use. Yet clay lands, possibly from their lower price, seem to be generally chosen for cemeteries; all those around London with very few exceptions, being of this description, though in some places good gravelly sites might have been found within a mile of those unfortunately selected. At Finchley the soil, though not gravel, appears likely to possess active nitrifying properties, being of a soft, friable, loamy character.

BERI-BERI IN THE FIJI ISLANDS.

A VALUABLE contribution to the natural history of beri-beri is contained in the recently issued official reports on an outbreak of the disease which occurred in the year 1894 in the British colony of Fiji. All the patients were Japanese coolies, of whom about 300 were imported for the purpose of working on sugar plantations. Their ages varied from eighteen to thirty years, and they arrived in the colony on April 27th, 1894. It was understood that they were all medically examined in Japan, and on landing in Fiji they were, with few exceptions, a fine body of men, but during the first month of their employment, which was chiefly cane-cutting and draining newly-cleared land, there was a good deal of sickness among them, mostly malarial fever and diarrhœa. The first hospital case of beri-beri was admitted on May 30th; in the month of July at least seventeen of the men complained that they were suffering from kakke, the ordinary name for beri-beri in Japan, where it is well known to be endemic; and in the middle of November there were more than 220 cases. There were in all 268 Japanese known to be attacked, of whom 65 died, and in February, 1895, the whole of the survivors were sent back to Japan. The disease was entirely confined to these immigrants, not spreading either to the Indian labourers who worked on the same plantations with them or to the Fijian inhabitants of the villages. The Japanese were lodged in well-ventilated houses, all of which (with one exception) were constructed of wood and were spacious enough to allow at least 330 cubic feet to each occupant. After their departure these buildings as well as the hospitals were washed with a solution of corrosive sublimate of the strength of 1 in 1000, to which strong hydrochloric acid was added. Two days later the buildings were well washed with hot water and soap and left open for a week, after which the washings with corrosive sublimate and soap-and-water were repeated. They were then occupied by Indian coolies among whom no cases of beri-beri appeared during the eleven months that elapsed up to the date of the report. The colonial medical officers devoted much attention to the relations existing between beri-beri as it appeared in this epidemic and other diseases which either simulate it or have passed under the same name. They conclude that it is independent of scurvy, pernicious anæmia, or ankylostomiasis and that it is a specific neuritis affecting the motor and sensory nerves, peripheral at first, but afterwards involving muscles and vital organs supplied by the sympathetic system. It causes death either by paralysing the heart and respiratory muscles or by choking the lungs and other viscera with the œdematous effusion to which in one class of cases it gives rise. The most usual preliminary symptoms were a feeling of heaviness and weariness in the legs, numbness of the calf muscles, slight œdema over the crest and inner surface of the tibia, loss of appetite, giddiness, headache, shortness of breath, palpitation, rapid pulse, and digestive disorders. With respect to the motor paralyses, the calf muscles were generally first affected, then the peronei and the flexors of the feet and toes. The muscles of the hands and fingers were usually the next group affected. As a rule the patellar reflex was early impaired and with the progress of the disease wholly suppressed, some cases, however, with well-marked motor impairment exhibited good patellar reflexes and in some the reflex was exaggerated. Cutaneous anæsthesia was constantly present over the calves, the ankles, and the dorsa of the feet, accompanied by pain in the deeper parts when firm pressure was made. In a few cases very small rod-shaped bodies were observed in the blood, but cultivation experiments were unsuccessful. The reports were printed at the Government press in Suva and submitted to the Colonial Government last January; they refer several times to articles which appeared in THE LANCET in 1881, 1886, 1887, 1890, and 1893, as well as to the former prevalence of beri-beri in the Japanese navy and its eradication as a result of dietetic improvements.

"SÆVÆ NOVERCÆ."

TWO particularly brutal step-mothers were alluded to under the above heading in THE LANCET of April 4th. The county bench at Hastings on April 18th supplied a most salutary sequel to one case. It will be remembered that a married woman named Edith Batt was severely censured by a jury who investigated the cause of death of a seventeen-months' old child, her step-son. The case has been taken up by the National Society for the Prevention of Cruelty to Children, and the woman was charged before the magistrates with having cruelly ill-treated the deceased child. The evidence was most revolting. One neighbour swore that prior to the defendant's arrival the child was fat and healthy. She had, she said, heard Batt say, "Die, you little ——! I should like to have your insurance money for a spree!" Injuries which she had noticed on the child's eye, arm, and leg were put down by the woman to accidental causes; and on another occasion Batt said to the child, "I wish you would die—you are a misery to yourself and everyone else." Another woman, a lodger, said she had frequently seen the child cruelly treated by frequent slapping and by being dashed upon the floor. Defendant, she said, held the child by the clothes behind and dashed him face downwards on the floor, which was of wood covered with oilcloth. This took place every day, but "she was not in the habit of interfering with other people" and so said nothing. This witness's daughter said she had seen Mrs. Batt push food into the poor child's throat until he began to choke, and that she had seen her slap the boy in the face while tied to a chair until blood flowed from the mouth. A fourth witness said the woman told her she hated "the little —— and wished he was dead," and after the inquest Batt had admitted "I have slapped him and would slap him again if he was alive." Mr. F. J. Lewis, St. Leonards, said death was due to localised meningitis caused by a blow on the skull. There were an injury on each side, bruises on the cheek, buttocks, and abdomen which must have been caused by direct violence and numerous

Digitized by Google

other injuries. The child had been insufficiently fed for some time before his death. Dr. T. P. Harvey, who assisted at the necropsy, agreed. The defence to all this was a denial of cruelty and allegations of spite and ill-feeling against the chief witnesses. The magistrates, however, thought it was a case of great and gross cruelty and sent the woman Batt to hard labour for six months.

THE NOTTINGHAM SCHOOL BOARD AND MEDICAL CERTIFICATES.

THE *Nottingham Daily Guardian* of April 18th, 1896, in its report of the proceedings of the Nottingham School Board relates that the following resolution was passed by the board by a large majority—10 votes to 2:—"That in all cases of illness being assigned as reason for absence of scholars and of a medical certificate being required to substantiate such excuse the board shall pay for the medical certificate requested." The Nottingham School Board has set an example of justice in this matter which cannot be too soon followed by all school boards.

CATERPILLAR ERYTHEMA.

ATTENTION has been directed by the interesting correspondence in these columns[1] to the occurrence of erythematous and urticarial rashes in susceptible individuals after handling certain hairy plants — primula obconica and sinensis. It seems that in these unlucky persons the sting of a primula is followed by unpleasant cutaneous results just as a painful rash is caused in everyone by brushing against the hairs of a stinging-nettle. It is well, therefore, for the practitioner to bear this cause in mind when dealing with cases of erythema on the hands and parts of the body accessible to the hairs. There is another very common cause which must also be borne in mind when the patient is a schoolboy or an entomologist. Many of the common hairy caterpillars in this country when handled "sting" with their hairs just as the nettle and primula do. The hair penetrates some layers of the skin and breaks off, leaving a little piece projecting. If the hand is passed over the face the stumps of hair projecting from the skin stin the face in a similar manner. Soon an intolerable itchin begins, more extensive than the parts actually irritated; vigorous rubbing goes on until in a short time the arms, face, neck, and often chest become covered with a red eruption in which minute nodules can be detected. The hairs and the poison may even be transferred (as Mr. Lawford has shown in the case of Bombyx Rubi) to the conjunctiva, the hair ultimately becoming encapsuled in a little nodule of fibrous tissue. The rash is often attended with considerable swelling and slight rise of temperature, and, as Dr. Dukes of Rugby pointed out,[2] may lead to an erroneous diagnosis of rötheln. It would be well if medical officers of schools warned the boys of the caterpillars which should not be handled and of the risk they run in rubbing themselves when the skin is irritated. The chief British offenders are the common "woolly bear," the caterpillar of the tiger moth (Arctia caia), and its near relations; almost all the Bombyx group, including the oak eggar, fox moth, drinker and lappet moths; and the Liparis group, including the common "gold tail" and "brown tail." The hair of some foreign caterpillars has much more severe effects. Gangrene has been reported from contact with the hairy Indian Shoa Pokâ, and the Australian Lasiocampa vulnerans is credited with producing fatal results. On the Continent there is a very common caterpillar, the Bombyx processionea, which fortunately does not appear to have reached this country. The erythema resulting from contact with it is followed by severe general symptoms, and in the case of one boy in the south of France, whose case was detailed in THE LANCET,[3] after a number of caterpillars had fallen on his chest while climbing a tree, there ensued violent irritation, general swelling, fever, somnolence, delirium, and death in a few hours in spite of energetic medical treatment. Although fortunately we do not meet with such severe cases in this country, the effects are so unpleasant to the victim and the diagnosis is often so difficult for the practitioner that a word of warning to those most likely to suffer will not be superfluous.

[2] THE LANCET, Oct. 29th, 1881.

MANCHESTER NIGHT ASYLUM.

AMONG the lesser Manchester institutions this fulfils a useful and beneficent purpose. As the report read at the annual meeting the other week says: "There always exist, and will continue to exist, numbers of people out of work, who are at times too poor to pay even for a night's lodging and who, rather than go to the workhouse wards, would prefer to stay all night under any shelter, however comfortless. These people are not paupers and do not wish to be pauperised, they are seeking work, and with that object come to and pass through our large towns." It is mainly to help such people with a night's lodging that this institution exists. It can give through the winter months, from October to March inclusive, "a warm and comfortable lodging, and fire and food, to one hundred and fifty people." Comparatively few women make use of it, perhaps because it is not so well known as it ought to be that there is a separate room for women, and partly because fewer women than men lead the wandering life often forced upon the latter by want of work. Last year 4702 persons were relieved. This can be done with an income of £200 a year, but from the deaths and removals of old subscribers an appeal for more funds has become necessary. At the end of the year the institution was in debt to the treasurer to the amount of £70.

"NATURE PLEASURES IN A RIVERSIDE GARDEN."

WE have on several occasions referred with pleasure to the papers which Mr. W. J. C. Miller, the registrar of the General Medical Council, contributes from time to time to "Nature Notes." Richmond-on-Thames is a little less than ten miles out of London, yet if we did not know the *locale* of the garden about which Mr. Miller discourses[1] we should be inclined to think of it as at least five times that distance from our smoky metropolis. The mere mention of evening primroses and clematis in Mr. Miller's picturesque language is refreshing to the weary town-dweller and the author evidently extracts from the contemplation of them a pleasure and delight which all must envy. Amongst feathered life too he is quite at home, and the stately birds which inhabit certain parts of our great river and which the poet addresses at eventide—

> "Day is dying; float, O swan, along the ruby river,
> Requiem chanting to the day; day, the mighty giver."

must call to mind, as they slowly drift past the garden, Wordsworth's lines:

> "The swan on still St. Mary's Lake
> Floats *double—swan and shadow!*"

Nowhere, says the author, can be better realised the song which Tennyson phrases:

> "Summer is coming, summer is coming, I know it, I know it, I know it;
> Light again, leaf again, life again, love again: 'Yes, my wild little poet.'"

And the life and songs of other birds in his garden are described in sympathetic and felicitous language. Such simple pleasures as these, which can be obtained by

[3] THE LANCET, July 26th, 1862.
[1] Reprinted from Nature Notes, April, 1896.

Digitized by Google

quiet contemplation of nature, cannot but help vastly to repair the waste of energy entailed by a busy life in an overcrowded metropolis rendered hideous by the discordant pandemonium to which we have long called attention. Such pleasures cost nothing but the training of an observing eye. The benefits, both moral and physical, are of untold value.

VACCINATION IN IPSWICH.

IT must be somewhat trying to the self-respect of boards of guardians, whose duty it is to enforce the Vaccination Acts, to be reminded of their responsibility, and perhaps even of their neglect, by sanitary authorities. Yet this has occurred over and over again the latest instance being at Ipswich last week, when the Public Health Committee of the Corporation, alarmed at the neglect of vaccination in the borough, considered it their duty to draw the attention of the guardians to the risk occasioned to the inhabitants of Ipswich by the presence of a large number of unvaccinated children. At the meeting of the guardians when this communication was brought forward Mr. Preston Thomas, one of the general inspectors of the Local Government Board, in answer to a guardian, who was evidently somewhat misinformed, put before them some of the arguments in favour of vaccination, and it is to be hoped that his words have not fallen upon absolutely stony ground. Mr. Thomas estimated from the vaccination returns that there were in all probability some 5000 unvaccinated children in Ipswich, and he pointed out that the presence of this inflammable material was a serious matter to those responsible for its existence. He observed that it was hardly to be expected that ignorant and careless parents would have their children vaccinated unless they were compelled to conform to the provisions of the Acts, which, he reminded the guardians, have neither been repealed nor suspended. We are glad to see, too, that one of the members endeavoured by a reference to the Gloucester calamity to impress upon the guardians the commercial aspect of neglected vaccination, and insisted that if an outbreak of small-pox occurred among the infantile population of Ipswich the guardians would be mainly responsible for it. We wonder how many of the Ipswich guardians have taken the trouble to study the question of vaccination or how many of them possess a copy of the Vaccination Acts? It is lamentably suggestive that the administration of the Vaccination Acts should be entrusted to a body who have to be reminded of their duties by the Public Health Committee of the corporation. Let us trust the warning may not be too late.

DEATHS UNDER ANÆSTHETICS.

AN example of this form of death is afforded by the loss of a patient at the Yarmouth Hospital the particulars of which have been kindly sent us by Dr. K. W. Monsarrat, the house surgeon. A man aged sixty-three applied for relief from urgent dyspnœa arising from pressure upon the larynx due to carcinomatous glands causing constriction. The primary cancer of the tongue had been successfully removed ten months previously. Owing to the laryngeal stenosis the man had several times been nearly asphyxiated. Tracheotomy was decided upon and chloroform was accordingly administered from a towel. The man went under in about four minutes, taking the anæsthetic well. As a preliminary to the operation the head was extended, a sandbag being placed under the neck. Dyspnœa at once increased, the face became cyanosed, and in a few seconds respiration ceased entirely. The operation was rapidly proceeded with and then artificial respiration was practised. The patient never rallied. Respiration ceased thirty seconds before the heart stopped. The operation not being one of emergency the anæsthetic was deemed advisable. Death was "due primarily to sudden paroxysm brought on by forcible alteration in the position of the neck and only secondarily to the anæsthetic." We are not told whether the faulty posture was at once rectified before the operation was proceeded with. Similar conditions arise in operations undertaken for the relief of goitre and have caused grave consequences. A very similar case is reported from Warrington. Unfortunately the particulars supplied are quite inadequate. The patient, a man aged sixty-three, applied for relief at the infirmary at Warrington. He had suffered from carcinoma of the throat for two years, and presumably stenosis had arisen as it was proposed to perform tracheotomy. The junior house surgeon gave chloroform. The quantity used and the method employed are not mentioned nor are any particulars given as to the symptoms which appeared. We are simply told that when the operation was commenced respiration ceased. The medical testimony given at the inquest showed, we are informed, that spasm of the glottis was the cause of death. The extreme importance of accurate and thorough accounts of all such fatalities being furnished to the medical press is too obvious to need to be dilated upon, and we regret that we have not received fuller details.

THE National Society for Aid to the Sick and Wounded in War has sent out two surgeons to Bulawayo to assist in the care and treatment of the wounded. The gentlemen selected are Mr. W. Greenwood Sutcliffe, F.R.C.S., and Mr. W. Redpath, M.R.C.S. Eng., L.R.C.P. Lond. Both of these gentlemen have been house surgeons at one of our largest metropolitan hospitals, and the former has also been house surgeon at the Hull Infirmary. They have taken with them a large supply of medical necessaries, including antiseptic dressings, &c., and will proceed to Bulawayo as rapidly as possible. They left Southampton by the s.s. *Moor* on Saturday last.

THE executive committee of the National Society for Employment of Epileptics announces that the foundation-stone of the Home for Women will be laid with Masonic honours by the Right Honourable Lord Addington, Provincial Grand Master of Buckinghamshire, assisted by the officers of the Provincial Grand Lodge, on Tuesday, May 26th, at 4.15 P.M., at the Colony, Chalfont St. Peter. A train leaves Baker-street at 2.29 for Chorley Wood Station, and carriages can be provided at the station for those who accept invitations prior to Thursday, May 21st. Reply should be made to the Secretary, 12, Buckingham-street, Strand, W.C.

A CONVERSAZIONE will be given by the Medical Society of London on Monday, May 18th, at the rooms of the society, 11, Chandos-street, Cavendish-square, at 9.15 P.M. The Oration will be delivered by Dr. W. H. Allchin on "The Breaking Strain" at 8.30 P.M. Music by the "Bijou" orchestra will be provided and smoking will be permitted at 10 o'clock.

THE third International Congress of Psychology will meet in Munich from Aug. 4th to Aug. 7th inclusive. The titles of 132 papers are announced already, several of them being by English and American writers. The general secretary is Dr. Freiherr von Schrenck-Notzing, Max Josephstrasse, Munich.

AN application for election as a member of the Pathological Society of London having been received from a duly qualified lady the question of the desirability of admitting female medical practitioners to the society will be submitted to the annual general meeting of the society to be held on Tuesday, May 19th.

Digitized by Google

WE have received a copy of a reprint of a paper by Dr. Pavy on the Physiology of the Carbohydrates, in which he once more questions the validity of Dr. Noël Paton's criticisms of his work. Dr. Pavy and Dr. Paton have done good service in showing how delicate and intricate is the task of unravelling the important subject of glycogenesis; and although this controversy has been somewhat unnecessarily prolonged the cause of physiology may, we trust, be advanced by the facts that have been brought to light. But that the subject has been finally determined cannot be admitted.

THE medical and surgical staff of the Victoria Hospital for Children, Tite-street, Chelsea, propose to give a course of lectures during the summer session upon the Diseases of Children. The lectures will be delivered in the board-room of the hospital every Thursday afternoon at four o'clock, and each will be followed by a demonstration of cases in the wards. Practitioners and students of medicine are invited to attend.

THE opening lecture of the summer session at the Hospital for Consumption and Diseases of the Chest, Brompton, will be delivered on Wednesday, May 6th, at 4 P.M., by Dr. C. Theodore Williams, on the Arrest of Pulmonary Tuberculosis. These lectures are open to students of the hospital and to all qualified practitioners, and will be continued on each Wednesday during May and June.

AMONG the Rand prisoners sentenced to a fine of £2000, two years' imprisonment, and a subsequent term of three years' banishment are, according to the *Daily News*, several well-known medical practitioners of Johannesburg — Mr. Hans Sauer, Mr. Duris, Mr. Davies, Mr. Mitchell, and Mr. Hillier.

WE have received the following telegram from Surgeon-Lieutenant-Colonel Lawrie:—"Discovered identical swarming Laveran's bodies in ordinary pus cells." We hope in an early issue to place before our readers Surgeon-Lieutenant-Colonel Lawrie's views on Malaria.

DR. ROBERT FARQUHARSON, M.P., is announced to take the chair at the annual dinner, on Oct. 18th of the St. Mary's Hospital Medical School. The introductory lecture will be delivered by Mr. Morton Smale, Surgeon to the Dental Department of the hospital.

THE second reading of the Public Health Bill—i.e., Bill for the abolition of quarantine—is set down in the House of Lords for Friday, May 8th. The second reading is to be proposed by Lord Harris.

H.R.H. THE PRINCESS OF WALES will open the bazaar and fête in aid of the new wing of the West London Hospital, Hammersmith, on Thursday, May 21st.

As we go to press we learn that Sir Frank Lockwood has stated in court that, terms having been arranged in the action of Kitson *v.* Playfair, the appeal will not be prosecuted.

THE ROYAL EYE HOSPITAL.—A dinner in aid of the funds of the Royal Eye Hospital (the Royal South London Ophthalmic Hospital, Southwark) was held on April 21st in the Whitehall Rooms of the Hôtel Métropole. Mr. James Bailey, M.P., took the chair and in proposing the principal toast said that he could speak of the hospital favourably from personal knowledge. Mr. M'Hardy (senior surgeon) responded and donations to the amount of £2059 were announced.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XVIII.

The Constitution of the Royal College of Surgeons of England.—A Sketch of its later History.—Wakley's Attitude towards the College.—The Reason for it.—An Outspoken Letter.

THE record of the first ten years of THE LANCET has so far shown itself to be a stormy one. Its publication was, in fact, attended with sufficient turbulence to satisfy even its Editor, whose early management had a good deal of the tread-on-the-tail-of-my-coat spirit about it.

Of the innumerable small quarrels that arose and were threshed out in these columns during this decade it will serve no purpose to speak. They would not be illustrative of anything in Wakley's character left uncovered by the Irish phrase just quoted, nor would they give the reader any particularly correct view of the medical profession of the day. They were but episodes in a contentious career, the border warfare incidental to Wakley's invasion of the privileges of the leaders of the profession. In contradistinction, his fight for the right to print the lectures of hospital surgeons and his determined attacks upon hospital practice when wrongly carried on must be looked upon as organised campaigns. These formed part of his policy of aggression as a reformer; indeed, with the third campaign, a description of which now follows, they constituted the policy by which he fulfilled the promises given in his prefaces to his readers. This third campaign was directed against the Royal College of Surgeons of England.

The most obvious and facile way of making Wakley's attitude towards the Royal College of Surgeons of England perfectly clear and, for that matter, of showing him to have been right in his main contentions would be to narrate the constitutional history of the College from the beginning; for nothing that he asked for had not an excellent historical reason for being granted, and everything that he clamoured against was an abuse of the ancient rights of the general body of the craft of surgery. But it would not be right to claim for Wakley that at the time that he commenced his crusade against the corporation of which he was a member—and so young a member—he knew the sound archæological ground on which he was standing. So far from knowing it, he never inquired into it, and had he been told that all his words and actions were justified by history he would not have considered his basis of operations solidified thereby. He was essentially the practical man, hot-blooded and rash in procedure, maybe, but eminently sensible in his demands. He saw that certain abuses flourished and he desired to cut them down. If history had been on the other side and his opponents had been able to claim for themselves a proud position of antiquarian rectitude he would not have been impressed thereby. He would only have said that times had changed and that it was imperative that the Royal College of Surgeons of England should change with them, putting it, frank Radical that he was, in phraseology that would have been unnecessarily irritating to the reactionary mind; he never would have modified his opinion.

An inquiry into the constitution of the College is hardly within the scope of this biography. All interested,

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., and XVII. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, respectively.

Digitized by Google

whether for practical or dilettante reasons, can find scattered up and down the pages of THE LANCET articles and letters upon every conceivable point in the history and working of the corporation, while the late Mr. J. Flint South's work "Memorials of the Craft of Surgery in England," issued after his death under the competent editorship of Mr. D'Arcy Power, is a mine of scattered information upon the subject.[2] Yet a brief recapitulation of certain facts in that constitution must be given in order that the reality of the abuses against which Wakley took the field may be properly comprehended. To do this it will not be necessary to go further back than the dissolution of the old Company of Surgeons. By the Act of 1745 it was enacted that the Master and at least one of the governors should be present at every Court, with one or two ordinary assistants, in order to constitute a quorum. It happened at the meeting held on July 7th, 1796, that in consequence of the death of one governor and the serious illness of the other no legal Court was possible. Notwithstanding this, the Master and some Assistants determined on proceeding to business. This rash action proved fatal to the Corporation. The opinion of counsel was taken, and there was no doubt that the Corporation was destroyed by the illegal construction of the last court. In the following year a Bill was brought before Parliament, at the instigation of the Court of Assistants, to indemnify the Court and to legalise its acts, as well as to procure the re-establishment of the Corporation under the name of a college. This Bill had passed through the House of Commons and had been twice read in the House of Lords before the members of the Corporation were aware of its purport. A petition in opposition to the Bill was at once prepared and presented to the House of Lords. This petition set forth that the Bill had been drawn up without the knowledge or sanction of the members of the late Company, who had not been convened to consider it. It further declared that the master, wardens, and assistants, without the knowledge or consent of the Company, had alienated the property of the Company, made purchases greatly beyond the extent allowed by law, and had been guilty of gross maladministration; that they had not taken one material step for the public good or the advancement of the science of surgery; that a certain number of the Court of Assistants had, as examiners, received for their private use a large share of the revenue of the Company; that if the Bill were to become law those persons who had been guilty of this maladministration would acquire absolute supervisal and control over the members and their affairs; that the ancient privileges of members would be annihilated, and their right of meeting in a General Court would be taken away; and that the Court of Assistants would be able to oblige members to swear to the observance of such laws as the Court might make, although the members themselves would have no voice in the making of these laws, and no choice in the appointment of those who should make them. Lord Thurlow, who took up the cause of those members who petitioned against the Bill, argued that the petitioners against the Bill had great reason to complain. Their privileges had been violated, and even their property invaded. He considered that however grating it might be to the ears of some people, meaning the Court of Assistants, they had the strongest title in the world to have their complaints heard with patience and attention. The result of Lord Thurlow's powerful intervention was that the Bill was thrown out in the last stage. But, in spite of the rejection of the Bill by the House of Lords, the discredited Court of Assistants of the defunct and dissolved Corporation did not despair; they continued to admit persons under letters testimonial, and though low in reputation and in funds, agreed on Dec. 13th, 1799, by a unanimous vote, to accept the charge of Hunter's Museum, for which Parliament had six months before voted a sum of £15,000. The next step followed as a matter of course: the Court of Assistants had now no difficulty, by the aid of courtly intrigue, in satisfying George III. that it was impossible to discharge its trust without some method of replenishing its finances. What Parliament had refused the King was easily prevailed upon to grant, and thus in the month of March, 1800, the College of Surgeons was established by a Royal Charter, which sanctioned most of the obnoxious provisions contained in the Bill rejected by the House of Lords.[3] The fact therefore stood out conspicuously in the negotiations which preceded and led up to the establishment of the College, that Parliament refused to pass a Bill which excluded Members of the College from a share in its government. Consequently, though it was and is true that Members have no legal right to the franchise by the Charter of 1800, they had and have at least a moral claim.

Such was the constitutional history of the Royal College of Surgeons of England, and it must be remembered that when THE LANCET was founded it was comparatively modern history, and the abuses had not had time to lose their distinctness of outline under any decent veil of antiquity, They were new and not hallowed by custom and years of acquiescence.

Wakley first fell foul of the Royal College of Surgeons of England because of a by-law which was passed in March, 1824, to make it compulsory for medical students to attend the lectures of certain hospital officials. The innovation appealed to him in two ways. Personally he was concerned because he was publishing these lectures in THE LANCET, and the contemporary medical press was, as narrated in the previous chapter, excessively disturbed in its sense of what was right thereby, and freely called him a robber. But if the lectures were compulsory for the students before they could take their diplomas the private character claimed for them by Abernethy and others was destroyed. A newspaper would have an undoubted right to report them, because it was to the public benefit to know whether instruction which the London medical man must willy-nilly receive was worth receiving. Lecturers chosen in this manner by the Council of the College were constituted public officials in their capacity as lecturers, and in addition to the importance and substantial fees thus ensured to them, could not claim all the privileges enjoyed by private individuals. In a second less direct way he was concerned in the working of this by-law. Some of the hospital surgeons appointed by the Royal College of Surgeons of England as the only persons whose lectures would be recognised as official charged their classes very large fees for attendance. Wakley had not been an affluent student, and had known many men much poorer than himself. He was always jealous of the rights of the poor man, and he inveighed against the extraction from the pockets of students of large fees for attendance upon the classes of certain men—not, as he asserted, the best men.

When he had got as far as this—as far, that is, as the statement that the best men were not selected to deliver these compulsory lectures—all the arguments which he had used against nepotism when attacking the domestic management of the large metropolitan hospitals came into service. He declared that the authorities of the College, by playing into the hands of the hospital surgeons, made of themselves a ring, so that the corporation, which ought to have existed for the good of its members at large, really only existed for its small class of governors and the officials appointed by them.

The official ring was thus arranged. The hospital surgeons

[2] See also a lucid and forcible little article by Mr. Tweedy, THE LANCET, March 23rd, 1889.

[3] THE LANCET, Oct. 30th and Dec. 11th, 1886.

Digitized by Google

appointed the lecturers to the medical school—that is, they appointed themselves, their relations, and the gentlemen who had paid them large fees to become their apprentices. The hospital surgeons were also the authorities at the College of Surgeons, that is they were the men who decided that the lectures of certain gentlemen should be compulsory for all medical students in London. The compulsory lectures were delivered by themselves, their relatives, or their apprentices. It was this corrupt arrangement against which Wakley worked. It moved him, as the nepotism that was prevalent at the Borough Hospitals moved him, to wrath and scorn, and his first attacks on the College had no historical foundation at all. They were consecutive to his attacks on the hospital lecturers who, though paid as public officials, desired to exclude the medical public from any participation in the benefits to accrue from hearing their words; and they were a rider to his proposition that the hospital surgeons who did not desire to see hospital reports in print were unskilful and prudently aware of their own limitations. But when the attack had been inaugurated on these lines the constitution of the College was attended to, its anatomy laid bare, and, as will be seen, Wakley's disclosures to the members of the unfair manner in which they were being treated by their rulers led to some sensational developments. These will be narrated in the chapters which follow, but it will not be out of place here to quote an open letter which appeared in THE LANCET as early as 1826, purporting to be addressed to the Court of Examiners of the College, but really designed to catch the attention of the members. The letter, as will be seen, summarises the more obvious grievances of the members, and was written by one of the ablest members of Wakley's staff, Mr. James Wardrop.

An Open Letter addressed to the Court of Examiners of the Royal College of Surgeons.

SIRS,—"If the members of the Court of Examiners and assistants of the Royal College of Surgeons are not too much employed in collating the Hunterian MSS. or at home listening to the chirping of cock sparrows,[4] or writing an oration on the splendid anatomical discovery of ordinary putrefaction they may perhaps find time to read this letter. We know that old men can recollect remote events better than those of later date. They can tell you what was done in such and such a year and will amplify all the circumstances; but they forget what happened in the last year. In other words, they can tell you what took place in their age of pleasure or in that of their ambition; they forget what they do in their age of avarice. It shall be my business to be their historian. I will endeavour to save their public actions from oblivion to receive the contempt and detestation of men of science in future ages. The court will well remember the following facts:—

"In the year 1797 the master, wardens, and assistants of the Corporation of Surgeons, without the knowledge or consent of the commonalty, presented a Bill to Parliament to elect the said corporation into a College. It was, in fact, to obtain a Bill of indemnity for squandering the property of the commonalty and trampling on their rights and privileges. Lord Thurlow, who had risen by his merit to the highest rank of his profession, saw immediately through the paltry artifices of this petty corporation. His lordship described their Bill as 'a miserable and wretched performance, in which the arrogance of the provisions maintained an equal contest with their absurdity.' The whole number of the Members at that period, exclusive of the court, amounted only to 500. The Bill had passed the House of Commons and had been twice read in the House of Lords before it was known to the commonalty. A meeting was called by a few spirited individuals and the number soon increased to 127. They petitioned the house against the further monopoly of this avaricious corporation, and at the third reading the Bill was rejected. The commentaries upon it, with the speeches of counsel, may be found in Woodfall's Parliamentary debates.

"Some curious facts were at that time elicited. The corporation were compelled to produce their accounts, and although, as I have said before, the number of the commonalty did not exceed 500, it was stated that since the passing of the 18th of George II. in the year 1744, the corporation had received in fees and quarterages and by other means the sum of £80,000! and that during the said period they had put £16,000 into their own pockets!!! What they could not get by Act of Parliament they have since obtained by charters. They are become a College and style themselves President, Vice-president, and Council; but the commonalty, who of course were not consulted about the charters, are still called Members. For my own part I would as soon be called a Member as a Fellow of such a College. They take our money, give us *ex post facto* laws, lock up our property, insult us with mock orations, live at our expense, and refuse to call us by our proper names!

"For the information of my professional brethren and fellow-sufferers I communicate this piece of intelligence: 'Every member from the moment he is admitted and has paid the fee of £22 to the court and the 5*s*. demanded by the beadle is as unequivocally entitled to the museum and the property of the College as any member of the court.'

"I need hardly remind you, Sir, that the magnificent collection of John Hunter was purchased by Government and that a loan of a large sum of money was supplied from the same source to erect a suitable building for its reception. Do you think the motive for such liberality was that twenty-one persons should have power to lock up the museum for eight months in the year? When their Bill was before the House of Lords it was said that they had a theatre without lectures and a library without books. It is true we have now some lectures on comparative anatomy and surgery; but the man best qualified to give the lectures on the former subject is doomed to fill the servile officer of conservator of the museum. They have also books, and some years ago Sir William Blizard promised that the library should soon be opened. We are still outside the door, however, and a part of the bust of Sir William, like the molten calf of the Israelites, may go down our throats (by the adulteration of bread or in the drinking of soda-water) before we shall see a book, especially the Hunterian MSS.

"The Museum is opened twice a week during four months in the year. The hours of admittance are from twelve to four o'clock. This does not extend to the whole collection, for the gallery is only accessible from twelve to two o'clock. Should the extensive and varied information and indefatigable kindness of the conservator of the museum, Mr. Clift, tempt an unfortunate individual to remain a minute after the clock has struck the hour his crime is announced by the loud and angry sound of the beadle's bell. This noisy warning is very quickly repeated, and lest he should not understand it the beadle calls out in a most autocratic tone, 'This way, sir.' The College member descends the steps muttering perhaps, as I have done, 'Any way but this way, sir.'

"If a knowledge of these facts will not rouse in the profession that spirit of opposition to the arbitrary power of the College which it is the object of these letters to excite I shall have the satisfaction to reflect that I have done my duty in making the attempt. "BRUTUS.

"Aug. 27th, 1825."

(To be continued.)

[4] Mr. Earle was nick-named "The Cock Sparrow."

ANNUAL REPORT FOR 1894 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

I.

THE third annual report recently issued by Mr. Shirley Murphy is a publication which deserves to be attentively studied by those who are interested in the health and welfare of the vast population of the metropolis. The appearance of this report, which relates to the year 1894, may perhaps seem to have been unduly delayed; but it should be remembered that the report in question is not that of a vestry medical officer, who advises his own sanitary authority alone, it is the report of the central medical officer superintending the forty-three sanitary areas of London, and being based on the separate contributions of as many local officers its

Digitized by Google

preparation cannot even be begun until the whole of the forty-three reports have been received from the vestries. The report for 1894 is arranged on the same general lines as those of its predecessors, hardly differing therefrom save in the amount and necessary variations of the letterpress.

The statistical data which accompany the county medical officer's reports differ from those published for the metropolis by the Registrar-General, chiefly in the fact that the latter deal exclusively with mortality, whilst the former take account in addition of the sickness which leads thereto, so far as this is ascertainable under the London Notification Act. The areas dealt with by these two authorities are not exactly co-extensive, the administrative county being somewhat larger than registration London. But although the difference in the two areas is not sufficient to appreciably affect the rates of mortality, still the want of uniformity is unfortunate, and will, we trust, be rectified before long. The statistical portions of the report are, as before, very complete and instructive. Passing over preliminary details respecting population, marriages, births, &c., we find that a lower death-rate is announced for London in 1894 than that of any year since 1837, when civil registration was first instituted. Much care has been taken in the distribution of deaths registered in institutions to the places from which the patients originally came and in correcting the district mortalities for these deaths as well as for the age differences in their several populations. Mr. Shirley Murphy exhibits an excellent method of utilising the life-table, published in a former report, for the purpose of comparing the mean rate of London mortality in the four years 1891–94 with that in the ten previous years. The death-rates at twelve groups of ages in the two periods are placed in two parallel columns of a table, a third column of which shows the difference per cent. between the rates at the several ages. From this table it is seen that whereas the mortality at all ages has declined in the more recent period, that of males from thirty-five to eighty-five years of age and that of females from forty-five to eighty-five have actually increased, the decline in the death-rate at all ages being mainly due to a lessened mortality at the earlier ages. Statements of this kind, however, give only a vague idea of the gain or loss to the community resulting from an altered death-rate, and it is in the possibility of obtaining a more tangible result that one of the chief uses of a life-table is exemplified. Mr. Shirley Murphy puts a case by way of illustration somewhat as follows. Assume that in a certain community 800 deaths occur in a year, half of which are among persons under twenty-five years of age, whose mean future lifetime is, say, thirty years, and that the remaining half of the deaths occur among persons over twenty-five years old, whose mean future lifetime is, say, fifteen years, then these 800 deaths will represent a total of (400 × 30) + (400 × 15) = 18,000 years of "life capital" *lost to the community*. Now suppose that in the following year 700 deaths occur in the same community, and that 600 of these deaths occur among persons under twenty-five years and the remaining 100 among persons over twenty-five, then the loss of life capital to the community will be (600 × 30) + (100 × 15) = 19,500 years. Thus, while there is a *saving* of 100 *lives* in the second year compared with the first, there is an actual *loss* to the community of 1500 years of "life capital." It is, therefore, apparent that the actual number of lives saved in any period is at best but a rough measure of progress, and that the value of *each life* gained or lost must be considered in order to arrive at just conclusions. From the London life-table (1881–90) Mr. Shirley Murphy has calculated the mean future life time of males and females in groups of ages, and these have been printed in tabular form in the report.

The difference between the two sets of figures obtained by comparing the deaths occurring in 1891–4 with those that would have occurred at the same ages, if the death-rates of 1881–90 had still been maintained, will be the number of lives gained or lost at each age by differences of mortality. If, therefore, the mean future lifetime at the several ages be applied to these differences the actual gain or loss may be expressed in "life capital." Another table (II.) shows that during the period 1891–94, as compared with the period 1881–90, there has been a mean saving of 1042 lives annually in London, and that this represents 79,606 years of "life capital" annually saved to the community.

In view of the serious increase recently observed in the proportion of children in the London population who are returned as unvaccinated, we are pleased to find that Mr. Murphy has devoted considerable space to the discussion of the relations of vaccination to small-pox. During the five complete years in which the notification of infectious diseases in London has been compulsory the reported attacks by small-pox have increased from 60 in the year 1890 to 2815 in 1893; and although the number has again fallen in the year 1894 to 1193, still even this latter number, in the vast population of London, imperfectly protected as it now is by vaccination, must be looked upon as a source of imminent danger. The disease appears to have been widely disseminated over the entire county of London, the small district of St. Olave being the only one in the area which was free from invasion throughout the year. The attacks were distributed over the whole period, but as many as 143 cases were notified in the last week of July. This exceptional incidence was mainly due to a serious prevalence of the disease in the district of Marylebone. Some of the Eastern districts, notably Bethnal Green and Poplar, suffered heavily in May and June, and the invasion of West Ham was probably associated with this circumstance. In many instances mild or unrecognised cases of small-pox served as centres for the infection of numerous persons. Mr. Murphy gives an interesting table received from the Asylums Board, which shows the state as to vaccination of the small-pox patients admitted during the year 1894. In this period 797 vaccinated patients were admitted and 252 persons without cicatrices, whilst 68 were admitted bearing no evidence as to vaccination. The difference in regard to case fatality is very striking amongst these several classes of patients. Thus, the 797 vaccinated cases included 136 under fifteen years old, and of these not one died, whereas of the 252 unvaccinated cases 192 were under fifteen, and of these 39 or 20 per cent. died. At the later ages (over fifteen years) the mortality amongst vaccinated persons, although high, was scarcely more than one-fifth of that prevailing amongst unvaccinated persons of the same age. In his two previous reports Mr. Murphy had drawn special attention to the large increase which had taken place in recent years in the number of unvaccinated children in London. In the present report he returns to the subject and gives a table showing the proportion of children born in London since 1881 who were stated in the returns of the Local Government Board to have been "not finally accounted for" as regards vaccination. These returns are worthy of serious consideration; they show that whereas in the year 1881 the proportion of children not finally accounted for by the vaccination officers amounted to not more than 5·7 per cent. of the total births, the proportion of unprotected infants has steadily increased ever since that date, until in 1894 it reached the dangerous figure of 18·4 per cent.

THE ANGLO-EGYPTIAN EXPEDITION.

THERE is not much to chronicle with regard to this campaign. The relief of the pressure upon Kassala, which was one of the main objects of the expedition, seems to have been attained, the attention of the Dervishes having been directed from that position to the Nile and Suakin. But very little is really known of Osman Digna's whereabouts, his plans and intentions, or of the strength of his forces. The accounts given by tribes friendly to the British or by scouts and deserters are not, of course, reliable; but so far as there is information it would seem that the Dervish forces are animated by a very different and less unanimous spirit than that which obtained among them in the earlier campaigns on the Nile and in the Soudan. They appear to have been disheartened by recent reverses, and it is stated that they are in some straits as regards provisions for themselves and forage for their horses and camels. Nothing seems to be known at headquarters in India as to the dispatch of any native troops for Suakin, and it certainly does not yet seem to be settled that any portion of the Indian army will be sent to this station or Egypt. It is very gratifying to report that the men of the North Staffordshire Regiment are in good health and excellent spirits and that their discipline and behaviour have been exemplary. There were by the latest intelligence some fifty men of the regiment on the sick list. The heat is now great, reaching 114° F., but there is generally a slight breeze; still, the excessive heat is

Digitized by Google

much felt by the troops. We are very glad to learn that ice machines are being erected, for plentiful supplies of ice are a matter of necessity. A large amount of hospital accommodation has been provided at Wady Halfa and the other stations for the sick of the expedition, and it will very probably be needed, for the percentage of sick may be fairly expected to be high during the hot months. Sharp attacks of heat fever and heat stroke will be common, and for these supplies of ice must be forthcoming. No mention is made of the occurrence of enteric fever among the force. We are not told what is the exact nature of the accommodation provided for the troops, but thick or heavily thatched roofs will be required as a protection against the sun. The mud huts that have been used on previous occasions in Egypt proved very good. The telegraph has now been completed to Akasheh and the laying of the railway line is actively proceeding. It is generally assumed that Sir Redvers Buller will be in supreme command of the Anglo-Egyptian force when the advance on Dongola takes place. According to an article in the *Fortnightly Review* it is stated on unimpeachable authority that Lord Cromer has been, and is, in favour of the advance, which will no doubt take place as soon as the season is considered favourable. When the work of the expedition is accomplished it will be found that from first to last the labour entailed will have been very considerable and the undertaking an arduous one.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

THE annual report of the council, which will be presented to the members at the general meeting to be held at the Frascati Restaurant, 26, Oxford-street, W., to-day (Friday), at 5 o'clock P.M., states that although the society has had the good fortune to avoid any very expensive lawsuits in the past twelve months, there has nevertheless been a large amount of work done on behalf of its members, and very many cases have been dealt with and brought to a satisfactory issue. Several members have been assisted in putting a stop to slanders which were being circulated to their detriment, ample apologies being given by those responsible for the slanders. The society intervened in a dispute between the staff and managing committee of a hospital, the outcome being in the main satisfactory. In addition to other matters dealt with by the society, advice has been given to many members in a great variety of difficulties such as so frequently befall medical men. Several cases of "covering" have again this year been reported to the General Medical Council. The society has been the means of exacting penalties from several unqualified practitioners, and has done much in the direction of suppressing quackery.

The council are pleased to be able once again to call attention to the satisfactory financial position of the society. The annual balance sheet shows that on Dec. 31st, 1895, the total outstanding liabilities of the society amounted to the sum of £25 11*s.* 3*d.*, whilst the amount of cash in hand and with the society's bankers amounted to £151 9*s.* The fact that the third annual balance sheet of a society such as this should show a clear cash surplus of £125 17*s.* 9*d.* is one which will speak for itself.

THE ROYAL ACADEMY.

THE 128th exhibition of the Royal Academy of Arts will strike the visitor as a more level display of talent than usual. If there are no startling successes, if there is no picture whose theme or treatment, or happy combination of both, marks it out at once as a "picture of the year," there are certainly fewer hot, crude, thoughtless works than might be expected, taking into consideration the large number hung and the curious conditions of their hanging.

The popular Academicians and prominent painters are represented by typical pictures. No one could mistake Lord Leighton's "Clytie" for the work of any other brush, and its appearance on the walls of Burlington House is a pathetic reminder of the loss recently sustained by English art. The new President has a curious, weird, and striking work, "A Fore-runner," in the first gallery; it is a reversion to his early style. Mr. Sidney Cooper paints cattle as deftly as ever—see "Mist Clearing Off" in the second gallery. Mr. W. P. Frith's little highly-finished picture, "Juliet and the Nurse," belongs to a class of work now looked upon as old-fashioned, but certain to survive much of the more suggestive splutterings of his extreme juniors. Mr. Swan sends some admirable leopards, and Mr. Stanhope Forbes in "The New Calf" reminds the casual eye strongly of the picture which not so long ago won him immediate fame and an Associate's honours. Mr. Sargent sends the portrait of the year and it depicts the man of the year. His "Joseph Chamberlain" is certain to attract immense and well-deserved attention.

There are several portraits on the walls of men well known in the medical world; in fact, there are more portraits of members of our profession than of any other class. The best of these is Sir John Millais's "Sir Richard Quain." It is a quiet, distinguished, and lifelike little work, unconventional but natural. The President of the General Medical Council is shown in profile, and the expression of the face is reflective, even to seriousness. The presentation portrait of Sir Joseph Lister by Mr. J. H. Lorimer hangs on the line in Gallery X. and has one unmistakable merit, it is a remarkably good portrait; but there is nothing distinguished about the treatment, and to our mind the artist has not quite risen to his subject. If this is the case with the picture of Sir Joseph Lister it is emphatically so with Mr. Ouless's portrait of Sir Henry Acland. Sir Henry Acland's friends will forgive us if we say that his arduous busy practical career has never been able to detract from an exceedingly striking and picturesque exterior. Mr. Ouless's representation is the portrait of an able man, but would not allow those who do not know to guess that it was also the representation of a very distinguished-looking man. One of the best portraits in the gallery is by Mr. Herkomer, the subject being Dr. J. Leon Williams, whose learned paper on the minute structure of dental enamel recently communicated to the Royal Society we publish in our columns this week. The portrait is hung in a fine position and is a good likeness and a truly artistic picture. There are one or two portraits of medical men which are very distinctly of the presentation stamp. Mr. Ouless's "Dr. W. M. Dobie" and Mr. Luke Fildes's "Mr. Frederick Treves" are cases in point. Both are faithful representations of their subjects, but neither can be said to have much claim to be considered great pictures. Mr. Stanhope Forbes's "Sir Peter Eade" in Gallery VIII. is a much more inspiriting piece of painting. There is an excellent portrait of Dr. Edward Liveing, the Registrar of the Royal College of Physicians, by Miss S. E. Rands, which hangs in a good place in the First Gallery; while Mr. Fildes's "Dr. Thomas Buzzard" is also a careful and scholarly piece of work, giving, however, a good deal of austerity to its subject.

Things medical, we are glad to say, have not recommended themselves much to the exhibitors in this year's Academy, for the pathos to be got from the representation of the sick bed is generally rather cheap. Mr. Herkomer portrays a district nurse taking out a child for her first walk after a long illness, and it must be admitted that the child looks uncomfortable, but the nurse does not seem to us to be supporting her patient in a particularly effective manner.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6783 births and 4062 deaths were registered during the week ending April 25th. The annual rate of mortality in these towns, which had been 20·0 and 19·0 per 1000 in the two preceding weeks, rose again last week to 19·5. In London the rate was 19·3 per 1000, while it averaged 19·7 in the thirty-two provincial towns. The lowest rates in these towns were 11·6 in Swansea, 13·5 in Cardiff and in Huddersfield, 13·6 in Leicester, and 13·8 in Brighton; the highest rates were 23·3 in Liverpool, 24·7 in Oldham, 25·6 in Preston, 26·2 in Salford, and 27·8 in Manchester. The 4062 deaths included 699 which were referred to the principal zymotic diseases, against 666 and 635 in the two preceding

Digitized by Google

weeks; of these, 297 resulted from measles, 231 from whooping-cough, 64 from diphtheria, 40 from scarlet fever, 33 from diarrhœa, 33 from "fever" (principally enteric), and 1 from small-pox. The lowest death-rates from these diseases were recorded in Preston, Halifax, Brighton, and Bradford; and the highest rates in London, Oldham, Birkenhead, Manchester, and Sunderland. The greatest mortality from measles occurred in London, Birkenhead, Manchester, Oldham, and Sunderland; from whooping-cough in London, Croydon, Liverpool, Bolton, and Manchester; and from "fever" in Swansea. The mortality from scarlet fever showed no marked excess in any of the large towns. The 64 deaths from diphtheria included 41 in London, 5 in Birmingham, 3 in Liverpool, 3 in Manchester, and 3 in Leeds. One fatal case of small-pox was registered in Bristol, but not one in any other of the thirty-three large towns. There were 16 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 20th inst., against 23, 21, and 16 at the end of the three preceding weeks; 8 new cases were admitted during the week, against 2, 5, and 4 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2534, against 2676, 2587, and 2527 on the three preceding Saturdays; 236 new cases were admitted during the week, against 186, 226, and 201 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had risen in the three preceding weeks from 270 to 328, declined again last week to 287, and were 79 below the corrected average. The causes of 50, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Nottingham, Salford, Leeds, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·7 and 19·0 per 1000 in the two preceding weeks, rose again to 19·9 during the week ending April 25th, and slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·1 in Aberdeen and 17·1 in Dundee to 21·0 in Greenock and 22·5 in Leith. The 580 deaths in these towns included 30 which were referred to whooping-cough, 12 to diarrhœa, 10 to scarlet fever, 9 to measles, 4 to "fever," 2 to diphtheria, and not one to small-pox. In all, 67 deaths resulted from these principal zymotic diseases, against 91 and 56 in the two preceding weeks. These 67 deaths were equal to an annual rate of 2·3 per 1000, which was 1·1 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 29 and 21 in the two preceding weeks, rose again to 30 last week, of which 21 occurred in Glasgow and 4 in Aberdeen. The deaths referred to scarlet fever, which had increased from 5 to 7 in the three preceding weeks, further rose to 10 last week, and included 4 in Glasgow, 2 in Edinburgh, and 2 in Dundee. The 9 fatal cases of measles corresponded with the number in the preceding week, and included 5 in Glasgow and 3 in Dundee. The deaths referred to different forms of "fever," which had been 12 and 7 in the two preceding weeks, further declined to 4 last week, of which 2 occurred in Glasgow. Of the 2 fatal cases of diphtheria 1 was recorded in Dundee and 1 in Leith. The deaths from diseases of the respiratory organs in these towns, which had been 110 and 109 in the two preceding weeks, rose again to 120 last week, but were 25 below the number in the corresponding period of last year. The causes of 36, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 25 5 to 20·6 per 1000, rose again to 23·3 during the week ending April 25th. During the past four weeks of the current quarter the death-rate in the city has averaged 23·7 per 1000, the rate during the same period being 19·2 in London and 17·6 in Edinburgh. The 156 deaths registered in Dublin during the week under notice showed an increase of 18 upon the number in the preceding week, and included 4 which were referred to the principal zymotic diseases, against 10 and 6 in the two preceding weeks; of these, 3 resulted from whooping-cough and 1 from scarlet fever, but not one either from small-pox, measles, diphtheria, "fever," or diarrhœa. These 4 deaths were equal to an annual rate of 0·6 per 1000, the zymotic death-rate during the same period being 4·3 in London and 1·3 in Edinburgh. The 3 fatal cases of whooping-cough exceeded the number in any of the six preceding weeks, while the mortality from scarlet fever was below that recorded in any recent week. The 156 deaths in Dublin last week included 30 of infants under one year of age, and 45 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed an increase upon the numbers recorded in recent weeks. Five inquest cases and 6 deaths from violence were registered; and 63, or more than a third, of the deaths occurred in public institutions. The causes of 14, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-CAPTAINS SKERRETT and Kearney have embarked with the reinforcements for the Cape. Surgeon-Colonel Preston has arrived from Hong-Kong and proceeded to Dublin as Principal Medical Officer in Ireland. Surgeon-Lieutenant-Colonel Wolseley has resumed his duties at Wadley on return from Ashanti.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel John Peter Hamilton Boileau, M.D., F.R.C.S.I., is placed on retired pay. Surgeon-Major Arthur M. Kavanagh, from half-pay, to be Surgeon-Major, vice A. H. Morgan, D.S.O., retired, with precedence next below Surgeon-Major J. D. Day, M.B.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions among the officers of the Indian Medical Service:—To be Surgeon-Colonel: Brigade-Surgeon-Lieutenant-Colonel Terence Joseph McGann, Madras Establishment. Surgeon-Lieutenants to be Surgeon-Captains: *Bengal Establishment:* Charles Milne, Vivian Godfrey Drake-Brockman, William Young, John Joseph Bourke, George Yeates Cobb Hunter, Bernard Robert Chatterton, Cedric Barkley Prall, Charles Edward Williams, John Norman MacLeod, Walter Holland Ogilvie, Thomas Alfred Ollivant Langston, Richard Heard, Edgar Rowe Parry, Walter Hood Orr, and Paxton St. Clair More. *Madras Establishment:* George Bidie and John Plowden Morton. Her Majesty has also approved of the retirement from the Service of the undermentioned officers:—Surgeon-Major-General Peter Stephenson Turnbull, Bombay Establishment; Brigade-Surgeon-Lieutenant-Colonel Colin William MacRury, Bombay Establishment; Surgeon-Lieutenant-Colonel Benjamin Evers, Bengal Establishment; and Surgeon-Lieutenant-Colonel John O'Neill, Bengal Establishment.—*London Gazette.*

The following promotions are made, subject to Her Majesty's approval:—*Bengal Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels: Arthur Tomes, M.D., William Arthur Mawson, Sorabshaw Hormasji Dantra, Henry Hamilton, Bernard Doyle, Robert Cobb, Augustus Edward Stephens, and William Hotson Cadge. Surgeon-Captains to be Surgeon-Majors: John Henry Tull Walsh, Harold Hendley, Hormasjee Edaljee Banatvala, George Herbert Fink, and William George Patrick Alpin. *Madras Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels: John Maitland, George Lemon Walker, Charles Lethbridge Swaine, and Maurice Henry Smith. *Bombay Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels: John Macgegor, Alexander Kenneth Stewart, William George Hume Henderson, Kharshedji Ardeshir Dalal, and Henry Walker Butler Boyd.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Surgeons:

Digitized by Google

H. Elliot to the *Marathon*: J. A. Keogh to the *Australia*. Surgeons and Agents: J. H. Spreate at Llanwit; C. M. Kemp at Shoreham and Southwick; M. A. Lyden at Costello Bay and Spiddal; S. Killen at Carrickfergus; J. H. McAuley at Ringsend.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Frederick H. Appleby to be Surgeon-Major.

YEOMANRY CAVALRY.

Nottinghamshire (Southern Nottinghamshire): Surgeon-Captain J. F. D. Willoughby resigns his commission,

VOLUNTEER CORPS.

Artillery: 1st Ayrshire and Galloway: Alexander John Mackintosh, M.B., to be Surgeon-Lieutenant. *Rifle*: 5th (Isle of Wight, Princess Beatrice's) Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant K. W. I. Mackenzie to be Surgeon-Captain.

THE HEALTH OF THE DUTCH INDIAN ARMY.

In the April number of the *Archives de Médecine Navale et Coloniale* Dr. H. Gros supplies an interesting *résumé* of the medico-statistical report[1] compiled for the year 1894 by the medical department of the Dutch army stationed in the East India islands, otherwise known as Insulinde and Malaysia. In his paper Dr. Gros enters considerably into detail, but with a view to exhibit at a glance the principal facts and contrasts adduced we have constructed the subjoined tables:—

Vital Statistics of the Dutch Troops serving in Insulinde.

1894.	Strength.	Morbidity. Cases.	Morbidity. Per 1000 of strength.	Mortality. Deaths.	Mortality. Per 1000 of strength.	Loss by invaliding, &c., per 1000 of strength. Discharged on medical grounds.	Relegated to light duty.	Sent to Europe for change.	Sent to local sanatoria.
Europeans	16,631	29,493	1755	272	16·35	14·66	14·66	26·44	19·21
Asiatics ...	20,832	29,013	1392	478	22·94	73·06	8·73	*Nil.*	9·74
Africans ...	68	130	1917	?	?	—	—	—	—

Total loss from all causes—

Europeans	93·32
Asiatics	114·47
Africans	—

Chief Causes of Mortality.

	Percentage of total deaths. Europeans.	Asiatics.
Killed in action or died from wounds	29·41	9·22
Paludal affections	19·89	11·92
Intestinal diseases	17·28	5·02
Suicide	5·14	0·41
Beri-beri	4·41	46·88
Respiratory affections	2·94	3·13
Enteric fever	1·10	?

No deaths from tetanus, hydrophobia, or diphtheria occurred during the year; and, unlike our experience in India, the ravages of typhoid fever were comparatively slight. Under diseases of the nervous system are included five cases of sunstroke in Europeans. Two Asiatics suffered from leprosy and two more from cholera, the latter cases proving fatal. Dr. Gros concludes his article with graphic charts representing the march of the chief causes of disability during the past five years—namely, malaria, beri-beri, and venereal affections. That referring to the beri-beri shows a lamentable state of affairs.

TORTOISE TENTS FOR THE ARGENTINE GOVERNMENT.

A number of interested persons, including Surgeon-General Sir Guyer Hunter, Surgeon-Major-General Jameson, Surgeon-Major-General Taylor, and Surgeon-Colonel Gubbins, assembled at the works of the Military Equipment Stores and Tortoise Tents Company at Battersea on April 23rd to inspect a collection of tortoise army hospital wagons and tents which the company has just completed for the Argentine Government. The South American Republic Medical Inspector, Dr. Albert Costa, was also present. On one side of the grass plot adjoining the firm's manufactory thirty of these tortoise army hospital wagons were drawn up in line, and on the other eighteen of their tents were pitched, while the centre of the ground was occupied by the "Congo" and military stoves, their utility, weight, and component parts being severally described by the officials present. The hospital wagons appeared good, serviceable vehicles, differing but little from the pattern in use in our own service. Their covering, however, instead of being a fixture from the sides of the wagon, consisted of a loose tortoise-shaped tent, the sides being folded in and strapped to the top rail of the vehicle. When required, by just disengaging the straps the folds can be carried outward, and by means of half-inch ropes and pegs form a serviceable and water-proof tent. There were in addition two elongated cylindrical metal water receptacles to every wagon, one of which was carried beneath and just behind the shaft of the cart. Each of these water barrels contained sixty pints of fluid. On removing the lid of one of them a partition was noticed about three or four inches from the rim, in the centre of which was a hole for the filling and emptying of the barrel, and into the aperture was screwed a metal cup for use when required. There was also a metal lip soldered on to the side of the cylinder to prevent waste of water when pouring it out. Two sizes of camp ovens were shown, the larger pair weighing some 500 lb., and they could only be carried in a wagon or on a camel's back. The smaller size, two in number, weighed when complete some 85 lb., and these appeared by far the most useful, as they could be borne on the heads of men and were capable of being put together in some two and a half minutes and of cooking food for fifty men. As regards the tortoise tents, with their sombre green-coloured water-proof texture, they are no doubt handy and very serviceable erections, but they are to a certain extent dark and gloomy within, and their poles, though admirably finished as far as workmanship is concerned, appear too fragile for the rough work incidental to campaigning; it may perhaps be doubted whether these tortoise tents are in any way superior to our own well-ventilated, square, roomy tents made on the old Indian principle.

MEDICAL AFFAIRS IN INDIA.

The Indian papers received by the last mail are pretty full of matters medical, including Surgeon-Lieutenant-Colonel Lawrie's address on the Malarial Parasite at the Grant Medical College, Bombay, and the discussion that followed its reading, references to subjects embodied in the late report of the Sanitary Commissioner with the Government of India, correspondence regarding M. Haffkine's methods of vaccination against cholera, and articles on the state of the medical services.

Adverting to one of these subjects we may say that Surgeon-Lieutenant-Colonel Lawrie is endowed with great energy and powers of work as well as the courage of his opinions. If he is able to establish his view as to the alleged mistaken notions entertained by European observers in regard to Laveran's parasite he will assuredly obtain all the credit he deserves. Shortly put, he contends that the microscopic appearances discoverable in the blood are not really due to the presence and metamorphoses of a parasitic element, but to changes brought about in the normal ingredients of the blood through the perverted function of a diseased spleen. His address consists of two parts: one of destructive criticism, in which he alleges that the observations of histologists in respect of the Laveran bodies are founded in error and are susceptible of a different explanation to that given by them, and the other constructive, in which he sets forth his views as to the part played by the spleen in malarious subjects, in the production and development of blood cells which in their career and appearances deviate from the normal and healthy standard and give rise, he alleges, to those appearances which microscopists have mistaken for those caused by a parasite—the plasmodium malariæ. We have just received the address and hope to publish it in an early issue of THE LANCET.

ROYAL UNITED SERVICE INSTITUTION.

Lord Knutsford presided at a meeting held in the Royal

[1] Geneeskundig Tijdschrift voor Nederlandsch Indie.

Digitized by Google

United Service Institution on April 24th to hear an address from Mr. J. Furley on the Convention of Geneva and the Care of Sick and Wounded in War. In the course of his lecture Mr. Furley said that the badge was undoubtedly abused, but this only proved the necessity of making the powers conferred by the Convention of Geneva universally known, and also placing some restriction on the assumed rights of benevolent neutrals. It was essential that the Red Cross should be equally respected by soldiers as well as civilians. He considered that we possessed in England the means, *personnel* and *matériel*, out of which an effective supplement to the Army Hospital Corps could be formed to a degree that had never been attained in any other country, much as we could learn from other countries in regard to its organisation and extension to the requirements of war.

THE SPREAD OF SMALL-POX.

We commend the following letter to the consideration of the authorities. Gloucester has suffered severely, and if its sins are not to be visited on other towns the danger which our correspondent refers to must be dealt with immediately.

To the Editors of THE LANCET.

SIRS,—The dates fixed for assembling of "old hands" for Militia trainings being now at hand, is it too much to ask what precautions, if any, have been taken to prevent the importation of small-pox into hitherto healthy districts by men coming from Gloucester or the neighbourhood? Might I suggest that where any man's last-known address was in or near Gloucester he should be given leave off this training unless he can produce a certificate of recent vaccination. The assembling of the county Militia has been abandoned, but there may well be men in other regiments who reside in the infected district and whose coming thence into a fresh place might be a source of danger, not only to their comrades, but to the population of the place where the training is held.

I am, Sirs, yours faithfully,

SANITAS.

PORTRAIT OF SURGEON-GENERAL SIR JOSEPH FAYRER, BART., K.C.S.I.

The subscribers to the portrait fund will be pleased to hear that the committee have invited Sir Joseph Fayrer to sit for his portrait to Mr. Sydney Hall. It is expected that the picture will be finished early in July, when it will be placed in the officers' mess at Netley. This portrait is a testimonial presented to Sir Joseph Fayrer by his brother officers of the army medical services and other friends and admirers as some recognition of the great services he has rendered by his writings and official life to the army and to the Army Medical School, of the Senate of which he was an active member for many years.

DEATH IN THE SERVICES.

Inspector-General Arthur Anderson, C.B., M.D., on the 26th ult. He entered the Army in October, 1835, as Assistant Surgeon, and was appointed Surgeon in December, 1845. He attained the rank of Surgeon-Major in 1854, of Deputy Inspector-General in 1858, Inspector-General in 1862, and retired on half-pay in 1867. He served in the Eastern campaign of 1854, and was present at the battles of Alma, Balaclava, and Inkerman, and at the siege of Sebastopol. He was Principal Medical Officer, 4th Division of Balaclava and Inkerman (medal with four clasps, Turkish medal). He was also created a Knight of the Legion of Honour. He was present at the capture of Canton in 1857 (medal with clasp).

THE MATABELE RISING.

Public attention has been absorbed by the state of affairs in South Africa and the exciting news about the results of the Pretoria trial and the sharp fighting in the vicinity of Bulawayo. The garrison of that place was not only holding its own, but had made some very successful sorties. The number of killed and wounded on the part of those defending Bulawayo is, compared with the losses inflicted on the Matabeles, small; but we know relatively nothing about the hospital arrangements in Bulawayo itself. It is believed that the place can be successfully held until relieved.

HONG-KONG.

According to telegraphic intelligence received at the Colonial Office the Governor of Hong-Kong reports seventy-five fresh cases of bubonic plague in the colony during the week ending the 28th ult., and the number of deaths during the same period as also seventy-five.

The Queen has granted to Mr. Sidney Langford Hinde, L.S.A. Lond., Médecin, Service d'Etat du Congo, Boma, Her Royal licence and authority to accept and wear the Medal for the Campagne Arabe, 1892–94, L'Étoile du Service, and the Cross of the Royal Order of the Lion, conferred upon him by His Majesty King Leopold II., King of the Belgians, in recognition of his services while actually and entirely employed beyond Her Majesty's dominions in the service of the Congo Free State.

The National Society for Aid to Sick and Wounded in War has, as mentioned in another column, sent two surgeons to South Africa for service in connexion with the troubles in Matabeleland.

Surgeon-Major-General James Jameson will take up the appointment of Director-General of the Army Medical Department on May 7th.

Correspondence.

"Audi alteram partem."

THE MIDWIVES REGISTRATION BILL.

To the Editors of THE LANCET.

SIRS,—We would not trouble you did it not appear that those who are supporting this registration of midwives fail to grasp the seriousness of its meaning. Moreover, the second reading of the Bill is fixed for an early day in May. The actual aim of the registration of midwives is to establish a semi-educated class of midwifery practitioners to attend women in their confinements, on their sole responsibility and without the direct supervision of a medical practitioner. If this proposal were enacted it would repeal the Medical Act, 1886, which enacts that if any person wish to lawfully practise any branch of medicine—say, midwifery, or even affections of the eye or skin—such person must study for at least five years the three subjects of medicine, surgery, and midwifery, pass stringent examinations in them, and be registered.

This education is the minimum requirement. Section 2 (2) of the Medical Act, 1886, enacts: "The standard of proficiency required from candidates at the said qualifying examinations shall be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery, and it shall be the duty of the Medical Council to secure the maintenance of such standard of proficiency as aforesaid." This period of study being necessary in the public interest, the action of those who propose to establish an inferior order of midwife practitioners threatens to repeal the Medical Act and to revert to the death-dealing system associated with early midwifery practice. This Act is a life- and health-saving Act. To practise midwifery with efficiency and with the least possible danger to the public the practitioner must possess a full and perfect training in medicine and surgery as well as in midwifery. A large proportion of women about to be confined and many newly-born infants suffer from complaints which require medical and surgical skill. This inseparable unity of the three branches of medicine is one of national import and was recognised as such by the Royal Commission (1882) on the Medical Acts, among whom were the late Bishop of Peterborough, Earl Camperdown, Sir G. Jessel, Sir W. Jenner, Sir J. Simon, Mr. Huxley, Sir W. Turner, and others. This Commission reported as follows: "Another grave defect of the licensing system lies in the fact that nearly all the medical corporations grant diplomas in medicine alone or in surgery alone. There is no point of medical reform on which there is so general an agreement as that the holding of a licence ought to imply the possession of a complete qualification for practice; that is to say, the attainment of a sufficient standard of proficiency in all the three essential branches of medical practice—medicine, surgery, and midwifery. It is our opinion that the holding of a licence ought to be conclusive evidence of sufficient proficiency in medicine, surgery, and midwifery."

To understand the meaning of this life-saving recommendation we would state that previously to the above date the Medical Act (1858) recognised three classes of practitioners—viz., those educated in and who practised medicine only, or surgery only, or midwifery only. As practitioners who were educated and licensed to practise only one of these three branches were called upon to treat patients suffering from complaints which they had neither been educated nor licensed to treat, this condition of affairs constituted a grave danger to the public health. Hence the final abolition of what was

Digitized by Google

known as the partially-educated practitioner—a class of practitioner whom Continental Governments are suppressing—but one whom those in favour of the registration of midwives now ask Parliament to resuscitate and so to bring back those horrors associated with childbirth when midwifery was divorced from medicine, when the lying-in chamber was often the first stage to the chamber of death, and when the Fellows of the Royal College of Physicians of London—to their everlasting disgrace be it told—reported to the Home Secretary in 1827 that the practising of midwifery was "an art foreign to the habits of gentlemen of enlarged academic education." This evil of partially-trained practitioners caused grave discontent among medical educational bodies. In 1877 the Royal College of Surgeons of England reported to the General Medical Council as follows: "As regards any revival of the old system, whether for male or for female candidates, the President would report to the Council that in their opinion the objections to such a course are insuperable. The President would remind the Council that the registrability of midwifery licences, independently of qualifications to practise medicine and surgery, has been brought under the notice of Her Majesty's Government by the General Medical Council as "a serious error in the Medical Act . . calculated to be injurious to the public interest and an error which should be corrected by legislation."

These historical facts show the dangers of the proposal. The supplying of the highest medical skill to all—especially to the poorer and working classes when "in the great pain and peril of childbirth"—is of great national importance if we would maintain the physical health of our population. When it is remembered that every day in England at least thirteen women lose their lives in childbirth, that one woman in every fifteen confined in the first labour dies, that one death in every ninety-five of the total deaths from all causes is due to childbirth, that from 1871 to 1894 at the very minimum at least 50,542 women died from childbed fever and at least 52,819 from the so-termed accidents of childbirth,—when the Registrar-General states that these figures "are in all probability very much understated," when we refuse to shock the public by giving facts showing the terrible sick-rate and chronic ill-health rates which follow what some are pleased to call "natural" labour, surely such undisputed realities are sufficient to give us pause. The present provisions are amply sufficient. Articles 182 and 183 of the Poor-law Commissioners of 1847 empower Guardians of the Poor to grant an order to any poor woman in her confinement so that the district medical officer may attend to her; while Article 1 of the general order of the Local Government Board, January, 1892, gives guardians power to appoint district nurses to nurse such women. The skilful nursing of these and their newly-born infants is of urgent necessity, and if those anxious to supply the poor with semi-educated midwife practitioners would use their efforts to put the above orders into operation the best results would follow. Also, if other voluntary lying-in medical charities followed the example set by the committees of the lying-in hospitals at Newcastle and Oxford—where medical practitioners and nurses are appointed in each district to treat and nurse those women who are not eligible for Poor-law medical relief and who are unable to pay the usual medical fees—great benefits would accrue. We are anxious to improve the training of all midwifery nurses and if need be to support a practical scheme for their local registration, and we do not take any objection to the registration of midwives provided they act as midwifery nurses only and under the immediate supervision of medical practitioners. We earnestly protest against the proposition—one so antagonistic to the interests of the public and the best traditions of the medical profession—that a semi-educated class of midwifery practitioners is quite good enough for the poor women and the wives of the working classes, while well-to-do women have the highest professional skill available for their confinements.

We are, Sirs, yours truly,

L. ATTHILL,
Late President of the Royal College of Physicians in Ireland; late Master of the Rotunda Hospital; Member of the General Medical Council.

G. W. BALFOUR,
Consulting Physician to the Royal Infirmary, Edinburgh; Consulting Physician to the Royal Hospital for Children.

R. BARNES,
Consulting Physician to St. George's Hospital, London; late President of the Obstetrical Society.

J. BARR,
Physician to the Northern Hospital, Liverpool.

D. C. BLACK,
Physician to the Public Dispensary; Professor of Physiology in Anderson's College, Glasgow.

C. CAMPBELL,
Surgeon to the Poor-law Infirmary; Public Vaccinator, Saddleworth.

T. CLARKE, C.C.,
Physician to the Consumption Hospital, Liverpool.

L. DRAGE,
Medical Officer of Health, Hatfield.

E. L. FOX,
Consulting Physician to the Royal Infirmary, Bristol; late Examiner in Medicine, University Oxford; Vice-president of the British Medical Association.

T. W. HIME,
Surgeon to the Hospital for Women; Lecturer on Midwifery to the Medical School, Bradford.

R. T. JONES, J.P., C.C.,
Medical Officer to the Poor-law.

R. J. KINKEAD, J.P.,
Professor of Obstetrics in Queen's College, Galway; Physician to the Galway Hospital.

R. MILNE MURRAY,
Assistant Physician to the Maternity Hospital; Lecturer on Midwifery at the School of Medicine, Edinburgh.

W. J. MOORE, K.C.I.E.,
Honorary Physician to Her Majesty the Queen; Honorary Surgeon to the Viceroy of India; Surgeon-General to the Indian Army.

P. REDFERN,
Emeritus Professor of Anatomy and Physiology in Queen's College, Belfast.

W. STOKES, KT.,
Surgeon-in-Ordinary to Her Majesty the Queen in Ireland; Surgeon to the Richmond Hospital, Dublin.

L. TAIT,
Consulting Surgeon to the Birmingham and Midland Hospital for Women.

W. THOMSON,
Vice-President of the Royal College of Surgeons in Ireland; Surgeon to the Richmond Hospital, Dublin; Member of the General Medical Council.

C. G. WHEELHOUSE, J.P.,
Consulting Surgeon to the Leeds Infirmary; Member of the General Medical Council; Vice-president of the British Medical Association.

W. WHITEHEAD,
Senior Surgeon to the Manchester Infirmary.

R. R. RENTOUL,
Liverpool.

To the Editors of THE LANCET.

SIRS,—Your leading article in THE LANCET of this week and the correspondence that has lately appeared on the subject bear pleasing proof that the question of legislation for midwives is now being considered on other than party lines, and that there is an attempt by the opponents and advocates of registration to find a way agreeable to both. It seems to be fairly well agreed that the present state of affairs is not to be tolerated and also that midwives must exist, for, putting aside fees, it would be practically impossible for the present number of medical men, even if they wished it, to attend all the confinements that take place; and if the number of medical men was sufficient there would not be sufficient general practice to support the medical men. The chief question at issue appears to be that of control—education and registration arranged. We still are confronted by the difficulty of individual control, which must be such that the midwife shall not usurp in any way the authority or position of the medical man, or practise beyond the limits that may be prescribed for her by law; this latter it is suggested and feared she will do for the purpose of her own pecuniary profit. With a view to prevent the possibility of this and at the same time to obtain the necessary control I would repeat my suggestion[1] that no midwife should practice except as the paid servant of some body, such as a board of guardians, a village nursing association, or a maternity charity; that these bodies should be compelled to adopt specified rules for her management and conduct; and that every such body should appoint a medical man or medical men as paid or honorary officer or officers, or make some arrangement for the payment of any medical man that the midwife may call to her assistance. I merely offer this as a suggestion for discussion. It appears to me a possible way of solving the difficulty of control and to remove the

[1] Brit. Med. Jour., 1895, vol. i., p. 1176.

Digitized by Google

chance of the danger that might arise from the greed of gain on the part of the midwife.

I am, Sirs, your obedient servant,

Freshford, April 27th, 1896. CHAS. E. S. FLEMMING.

THE BEAVEN RAKE MEMORIAL.

To the Editors of THE LANCET.

SIRS,—In response to a letter which you kindly inserted soon after the early and lamented death of Dr. Beaven Neave Rake, Superintendent of the Leper Asylum at Trinidad, a sum of £83 14*s.* has been collected. Of this sum 50 guineas were sent to Dr. Rake's widow, and the remainder will be presented to Mr. A. Lucchesi towards defraying the cost of a very beautiful bronze tablet which he has designed and executed, and which has been placed in the entrance hall of the Museum at Guy's Hospital. As there may still be some old Guy's Hospital men and other friends of the late Dr. Rake who may desire to add their names the subscription-list has not yet been closed. The names of those who have already subscribed are appended. The tablet allegorically represents "Medical Science" combating "Disease" and bears the following inscription:—

IN MEMORIAM
BEAVEN NEAVE RAKE, M.D. LOND.,
SUPERINTENDENT OF THE
ASYLUM FOR LEPERS, TRINIDAD, AND MEMBER OF THE ROYAL
COMMISSION OF INQUIRY INTO LEPROSY IN INDIA, 1892.
REMARKABLE FOR HIS SCIENTIFIC INVESTIGATIONS.
RESPECTED FOR HIS ZEAL AND HUMANITY, AND BELOVED FOR HIS
PERSONAL CHARACTER,
HE WAS CUT OFF BY FEVER IN THE
37TH YEAR OF HIS AGE,
AUG. 24, 1894.

We are, Sirs, yours faithfully,

PHIN. S. ABRAHAM, 2, Henrietta-street, Cavendish-square. } Hon.
GEO. R. BUCKMASTER, Fair Lawn, Teddington. } Secs.
P. H. PYE-SMITH, Treasurer, 48, Brook-street, W.

"THE EFFECT OF MUSCULAR WORK UPON THE ALKALINITY OF THE BLOOD."

To the Editors of THE LANCET.

SIRS,—As Dr. Hutchison has now, no doubt, seen my reply to Mr. Fotheringham in THE LANCET of April 18th, showing that my results as regards the above heading agree with his own, I need not say anything further on that subject; but in his letter to THE LANCET of April 25th he raises one or two other points on which I should like to say a few words. With regard to the reaction of normal perspiration I know that the statements of authorities differ, and I have contented myself with quoting their statements and pointing out that a fall in the acidity of the urine always accompanies marked perspiration, whether this is due to muscular exercise or a Turkish bath, and that the converse fact that suppression of perspiration causes a rise in the acidity of the urine has been pointed out by Sir A. Garrod.[1] Dr. Hutchison's statement is also opposed to that of Heuss,[2] who distinctly says that normal sweat is acid at the time of its discharge from the ducts. Dr. Hutchison's suggested explanation of the early fall of urea which exercise may produce does not seem to me to meet the facts of the case, for this fall of urea, as well as the fatigue which accompanies it, can be prevented by controlling the uric acid,[3] but if exercise is always accompanied by formation of ammonia to neutralise acids then there should be a fall of urea in every case and we should be unable to control it. I would further point out that Auerbach[4] has shown that though the carnivora have the power of forming ammonia to neutralise acids, this power is only possessed by man and frugivora to a very insignificant extent, this probably accounting, as I have said in my book with reference to my experiments on the excretion of uric acid in dogs, for the very different reactions of the urine, and probably also of the blood, in members of these different orders, and furnishing also a somewhat powerful lever for the argument that man is not by nature a carnivore. I was greatly interested in Dr. Hutchison's paper, and if there had been any real antagonism between his results and my own I should have noted it carefully for further investigation. May I point out a misprint in my letter in THE LANCET of April 18th, where in line 8 "function" should read *formation?* I am, Sirs, yours faithfully,

Brook-street, April 27th, 1896. ALEXANDER HAIG.

JUVENILE SMOKING: THE DUTY OF THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—Whoever is desirous of raising the status of the medical profession and of adding to its true dignity cannot do better than read the admirable address of Mr. Springthorpe, the President of the Public Health Section of the Intercolonial Medical Congress of Australasia, given in THE LANCET of April 25th. Mr. Springthorpe took a lofty view of the services which the physician can render to the State. In all matters relating to the preservation of the health of the people the nation looks to the members of our profession for light and leading. But we live by the treatment of disease; its prevention is in direct contravention of our interests. Nevertheless, medical men have not only never hesitated about sacrificing their interests for the public good, but they have been zealous and even enthusiastic in their efforts to promote the means of protecting and promoting the public health. The valuable and disinterested services thus rendered to the State have won for the profession much honour and no little dignity both at home and in the colonies. The profession has once more an opportunity of rendering a great—indeed, an invaluable—service to the State. Of late years an evil of the gravest kind has been extending in our midst, an evil which attacks not merely the physical but the mental and moral health of the nation. Juvenile smoking is spreading like an epidemic. Over twenty years ago the occurrence of sporadic cases induced the Editor of THE LANCET to speak out very plainly on the subject. He said: "Whatever opinions may be entertained as to the effects of moderate tobacco smoking on the adult, there can be none as to its deleterious influence on the boy. The molecular changes coincident with development of tissue are interfered with, slowed, if not arrested by tobacco." Facts were cited in proof of the physical injury thus caused, as were others clearly showing the mental damage inflicted. The experience of France and Germany was referred to, and the importance of hygienic instruction was urged. But since that time the evil has enormously extended. Lads are infatuated by the notion that the ability to "blow a cloud" is an indication of cleverness and it raises them considerably in the estimation of onlookers.

The advent of the cheap cigarette has, however, been the chief cause of the rapid spread of juvenile smoking of late. The Chancellor of the Exchequer in his recent speech on the Budget, referring to the large increase of revenue received from tobacco, said: "I believe it is mainly due to the great increase in the consumption of cigarettes, which are especially attractive to our youthful population." He added, "I am told of one manufacturer who makes two million cigarettes a day who hardly made any a few years ago." Thus it is not only that mere children are using tobacco, but they are using it in the worst possible form. Moreover, whilst most adults smokers are inclined to exercise some restraint over their smoking, the young are too apt to rush into extremes. It is impossible to estimate the injury which boys are thus doing to themselves. Surely something should be done, and done promptly, to put a stop to all this mischief. In some parts of Germany and in some of the United States laws have been passed prohibiting young persons under the age of

[4] Virchow's Archiv, vol. xcviii., p. 512.

Digitized by Google

xteen or eighteen from smoking and rendering it a punishable offence for anyone to give or sell tobacco to youths. Why should not the members of the medical profession move earnestly in this matter and urge on the managers of schools on the one hand the importance of special teaching, exposing the folly and viciousness of the practice of smoking, and, on the other hand, make such representations to Parliament and to the Government as may lead to efficient legislation? By taking the initiative the profession would do itself great credit and would serve the best interests of the country most effectively. I am, Sirs, yours faithfully,

R. MARTIN,
Senior Surgeon, Ancoats Hospital,
Manchester.

April 27th, 1896.

THE QUESTION OF MEDICAL DEFENCE."

To the Editors of THE LANCET.

SIRS,—Referring to Mr. Keele's letter in THE LANCET of April 25th on the above subject, I cannot think that the medical profession will regard his objections to the absorption of the Medical Defence Union by the British Medical Association as sound ones. He objects to the formation of a gigantic trades-union and of the tyranny of the few over the many. Union is what the medical profession has been striving after hopelessly for years, and if it is a good thing at all the larger it is the better. As for the tyranny, when in the same issue of THE LANCET I see that one medical man advertises his advent by the village crier and others subsidise insurance agents to advertise their clubs at a penny a week or less, and while mangles and medical attendance are curiously mixed up together at Walsall, I cannot but think that a little wholesome advice and tyranny if necessary might be useful to teach some members of the profession to practise their calling in a way that does not degrade the whole profession in the eyes of the public. After the tyranny which the profession has suffered for years from clubs and provident associations the yoke of the British Medical Association will be but a feather weight.

I am, Sirs, yours faithfully,

Warsop, Notts, April 27th, 1896. E. S. NUTTING.

"THE BATTLE OF THE CLUBS."

To the Editors of THE LANCET.

SIRS,—The Friendly Societies Medical Alliance met at Wednesbury Town-hall on Monday, April 5th. The following resolutions affecting the profession were submitted to the meeting and carried *nem. con.*:—

1. That these institutions shall be called Friendly Societies Medical Institutions, leaving out the word "Aid" existing hitherto.
2. Persons of all grades, irrespective of position, are cordially welcomed to join.
3. That no annual reports of the work of the associations be published in which is shown the total value of property acquired or in which is shown the salaries paid to medical officers, the number of prescriptions dispensed or the visits made by the medical officers, as these figures have been used against the friendly societies' medical institutions by the medical profession, whose power for evil might have been much greater had the system of publishing statistics been more universal. [This proposition of the Kidderminster Association was carried unanimously.]
4. That the application of the medical officer of Tonbridge Wells Friendly Society be refused, and if any further dissatisfaction on his part be shown a month's salary be given instead of a month's notice. [The application of the medical officer here was to the effect that he considered the surplus capital at the year's end after defraying all legitimate expenses should revert to himself.]
5. That the Alliance should be registered, and that the Parliamentary representatives of the constituencies in which large associations exist be interviewed with a view to effecting certain proposals submitted to the last meeting, thus giving friendly societies greater power over the profession.
6. In towns where private practitioners decide to ask for more for adults and juveniles than the lodges pay at present, these clubs should attach themselves to one of the Friendly Societies Medical Institutions, and in the event of the non-existence of such an institution the disaffected clubs should form one and leave their surgeons *en bloc*.

[At this stage a telegram was received from Lincoln stating that the medical officers of the institution there had resigned. A reply was sent advising the management what course to adopt under the circumstances.]

7. That a deputation be formed, consisting of Alderman Dickinson (Lincoln), Mr. Willement (Norwich), and the President, to wait on the General Medical Council and seek their opinion on the question in dispute.

Now, Sirs, this bit of intelligence will doubtless be very interesting to the whole of the profession and especially to those who have clubs and who live in a town where a friendly societies institution exists. The profession here may now know what to expect. It will appear to all your readers that there is either a deal of Freemasonry or timidity when the Alliance resolve not to publish reports showing their numerical and financial position, what they are worth and what they pay their officers. This sort of thing will certainly not tend to a better understanding between the clubs and the profession. Let the General Medical Council not forget this when they are interviewed.

I am, Sirs, your obedient servant,

April 27th, 1896. SOPHOCLES.

P.S.—I may say that this Friendly Societies Medical Alliance is a conference of delegates sent from various friendly societies medical institutions, especially from those referred to by your Special Commissioner in the articles which have appeared recently.

THE ASHANTI EXPEDITION.

(BY OUR SPECIAL WAR CORRESPONDENT.)

IV.[1]

The Troops in Health, their Feeding, &c.

ON arriving at the top of the Monsi Hill, which I found by barometrical reading to be about 1122 ft. above the sea level, we had hoped to obtain an extensive view of the surrounding country, but we were greatly disappointed in this expectation on account of the impenetrable character of the tangled and prolific undergrowth which clothed its summit. Previously to our advance the pathway up the side of the hill was most irregular as well as precipitous in places, with huge boulders and stony projections barring the way and causing considerable inconvenience to anyone attempting the ascent. But thanks to the activity of our engineering party, the sappers of which worked like navvies, the bush was speedily cleared away where required, the stones removed, and a nice wide zigzag road was prepared throughout. Our troops were by this act of thoughtfulness on the part of the executive ultimately enabled to perform the journey up with comparative ease and comfort. The morning on which I crossed the range was beautifully fine overhead, with a soft, balmy air from east-north-east; while a thick white mantle of fog was observed to envelop and hide from view the whole of the country beneath us. About a mile from the top there was a sound of water rushing over some stony projection on our left flank. Desirous of ascertaining its whereabouts I halted my carriers and pitched my tent for the purpose of enjoying some refreshment, as I had partaken as yet of nothing since starting from Abru Edru. While my breakfast was being prepared by my coloured servant I was enabled to make an examination of the locality. Pushing my way through some very thick undergrowth, during which attempt I suffered considerably from the "lawyers" (thin canes with long barbed thorns), I managed after a brief search to come across quite a charming little cascade, over the ledge of which some beautifully clear, bright, drinkable water was foaming and tumbling into a tortuous narrow streamlet below. Just above the cascade was evidently the spring oozing out from under a large block of granite. The streamlet, pursuing a tortuous course down the northern side of the Monsi Hill, finally reaches Kwissa, and from it our supply was obtained for the rest camp of that place.

I have borne testimony to the hard work done by our men in Ashantiland more than once, but it does not necessarily follow from what I have said that a soldier's life (even during campaigning) is one of "all work and no play." It is no more one of incessant fatigue and hardship than it is one of "all beer and skittles," as Tommy Atkins would express it. He has his time for work as well as his time for rest and recreation, and unless untoward and extreme circumstances combine to prevent it he generally manages to secure his fair share of the two latter. I am not quite sure that he thinks so. He will sometimes growl. Grumbling is a permissible qualification not alone restricted to the army or navy but observable in other departments as well, and may as a characteristic of good sound health be considered a sort of safety-valve to let off the superfluous steam when necessary. But grumble or not as he may, our red-coat—as well

[1] Nos. 1, 2 and 3 were published in THE LANCET of April 4th, 11th and 25th, 1896, respectively.

Digitized by Google

as our blue-coat, too, for the matter of that—when he does turn to, goes at his allotted quota of work like a man, and only those whose duties have called them again and again to serve as correspondents with an army in the field, and have watched the all-round performances of our men abroad, can legitimately estimate the sterling worth of the British metal or appreciate the true ring of the coin as represented in the "stuff" of which our English army is composed.

As there were 26,000 medical sick comfort diets supplied for use to the recent expedition, I may here state what each medical comfort case consisted of: 1 bottle of brandy, 1 bottle of whisky, ½ bottle of champagne, ¼ lb. of arrowroot, ¼ lb. of pearl barley, 2 tins of extractum carnis, ½ lb. of bovril, 3 tins of condensed milk (sweetened), 2 tins of unsweetened milk, ¼ lb. of best tea, 3 lb. of white sugar, 1 lb. of candles, ½ lb. of soap, ½ lb. of salt, ¼ lb. of pepper, ½ lb. of compressed coffee, ½ lb. of pea soup, ¼ lb. of mustard, besides a good corkscrew, knife and fork, tin opener, nest of three hospital measures, pepper castor, and mustard pot. At sea when on board transport ships the soldier's rations, including a free allowance of good drinking and washing water, are daily as follows:—

Sunday.—12 oz. of salt beef, 6 oz. of flour, 1 oz. of suet, 2 oz. of raisins, 12 oz. of biscuit, 4 oz. of sugar, ½ oz. of tea, and 2 oz. of preserved potatoes.

Monday.—12 oz. of preserved meat, 1 lb. of fresh bread, 4 oz. of rice, 2 oz. of sugar, and ½ oz. of tea.

Tuesday.—12 oz. of salt pork, ⅜ lb. of split peas, 1 oz. of vegetables, 12 oz. of biscuit, 2 oz. of sugar, and ½ oz. of tea.

Wednesday.—12 oz. of salt beef, 6 oz. of flour, 1 oz. of suet, 2 oz. of raisins, 1 lb. of fresh bread, 4 oz. of sugar, ½ oz. of tea, and 2 oz. of preserved potatoes.

Thursday.—12 oz. of preserved meat, 12 oz. of biscuit, 2 oz. of sugar, ½ oz. of tea, and 2 oz. of preserved potatoes.

Friday.—12 oz. of salt pork, ⅜ lb. of split peas, 1 oz. of compressed vegetable, 1 lb. of fresh bread, 2 oz. of sugar, and ½ oz. of tea.

Saturday.—12 oz. of preserved meat, 1 lb. of fresh bread, 2 oz. of sugar, ½ oz. of tea, and 2 oz. of preserved potatoes.

From a perusal of the foregoing it will be seen that the quantity of food served out to our soldiers is ample in quantity, if it be not always excellent in quality. Having had opportunities for years past of judging of the character of the provisions I should unhesitatingly say they are, as a whole, remarkably good and very little fault can be found with them. The tea used by the troops in the last expedition was pronounced excellent. The biscuits, although hard, were found to be of superior quality and were consumed for some time after leaving Cape Coast Castle—until, in fact, our camp bakery was established. When that department was got into working order fresh bread was served out to the men. I was presented with the first loaf baked, and it proved to be an excellent specimen of what our commissariat bakery can turn out. Unsweetened milk was chosen in preference to sweetened. It seemed to stand the heat better than the latter, which frequently passed into a state of butter. It was anticipated that during the march up country any quantity of animal and vegetable food would be procurable by purchase from the friendly natives, but in this hope we were sadly disappointed, and therefore the commissariat had wholly to rely on their stock of preserved provisions. No fresh meat of any kind could be obtained this side of Kumasi. At that place two days' rations of beef were, I believe, given to our men. Therefore tinned meat had to be consumed not only *en voyage* but also during the greater portion of the time the troops were on shore. Now very often a little of this preserved nitrogenous food "goes a long way" and not infrequently it turns out dry and stringy, as if all the juice had been squeezed out of it; and there is, moreover, a decided absence of fatty matter to render it as palatable and nourishing as it should be. In temperate climates men's appetites are good if they are in a fair state of health and they can eat well and relish whatever is put before them. When serving in the tropics, under a depressing and enervating temperature, appetite fails and becomes capricious to a degree, and it is just at such periods that something out of the usual routine is required; and if there was one kind or class of food more than another that helped to supply this desideratum during our recent campaign it was, I think, found in Maconochie's ration, recently introduced, and a small supply of which was served out to our officers and men. There was one complaint made concerning it as far as I could gather, and that was that "there was not nearly sufficient" to satisfy the demands of the men. For my own part, I have never been much impressed with the luxury of preserved meat of any kind, and felt some reluctance in asking for a supply of it from the authorities. But not being able to procure either a modicum of mutton, fowls, or even eggs from the natives in the villages through which we passed—all the sheep, chickens, and even pigs being driven away into the bush on the approach of our troops—I was compelled in dire necessity to requisition something eatable from the Government food stores. Amongst other things generously supplied were two tins of the ration above referred to. Contrary to my expectation the contents of each tin furnished quite a tender, juicy, savoury, nutritious and very sustaining meal, widely different from the stringy, tasteless preparations, without fat or any juice whatever, which had hitherto been tolerated for want of a more acceptable article. This ration appears to be a combination of moderate-sized pieces of beef, very tender, evidently cut from the primest parts, judiciously cooked (not done to rags), together with carrots, onions, and potatoes, conserved in delicious, well-seasoned gravy. There is, moreover, a certain quantity of fat introduced, and the necessary juices so essential for perfect mastication and assimilation are retained throughout the diet. In other preparations of the kind where vegetables have been conjoined the latter have turned out in a mashed-up and pulpy condition. Not so in Maconochie's; by some agency or other the pieces of vegetable are preserved in a solid and unbroken form. Every tin, moreover, contains a suitable quantity of nice brown gravy free from supernatant fat, and, from what I can judge, is equal to about half a pint of good beef-tea. No bone at all is introduced, therefore every twelve ounces of beef are equal to about seventeen ounces of meat supplied with bone. Each tin, I have ascertained, contains at least twelve ounces of good solid meat and weighs, with the vegetables and gravy, about one pound and three-quarters. Although animal and vegetable substances are incorporated in this meal the combination keeps quite fresh without any signs of fermentation being apparent, and seems to have withstood the effects of even a West African climate well enough. The bodily health- and strength-maintaining essentials in the shape of albuminoids, starchy, and fatty matters are one and all represented in the various items of its composition and so nicely blended that many of our invalids out in Africa were not only able to eat but, what is more essential, digest some of the meat minced up with its gravy and some breadcrumbs when in consequence of the capricious state of their appetites they could not touch other kinds of diet as served out to them.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

A Centenarian.

INSTANCES of exceptional longevity do not always stand the test of inquiry when closely applied to the antecedent history of the individual. Lately, however, there died in this locality one Antoine Mountsoy who on Jan. 6th completed his 109th year, the record being an authentic one. This remarkable veteran was born at Bordeaux in 1787, and when a boy was taken prisoner by the English with his father. He remained in England when his father returned to France and served in the navy five years. He worked a quarter-deck gun on board the *Queen Charlotte* at the Battle of Algiers in the year 1816, being badly wounded. He subsequently served on a whaler and after many hardships settled down eventually near Lichfield as a small carrier. He was well known and respected in the district. At his funeral on April 22nd Captain the Hon. A. C. Littleton, chairman of the Lichfield board of guardians and a naval officer, sent a Union Jack to be placed on the coffin of the old man as a tribute of respect to the memory of his former service.

The Pollution of the River Tame.

The recurring alleged pollution of this small river by the Birmingham Tame and Rea district drainage board has been a source of perpetual trouble to the authorities concerned. At the recent annual meeting of the Tamworth rural district council the difficulties of the subject were freely discussed. The district council expressed the opinion that the river was now in a condition so dangerous to health that in case of

Digitized by Google

some epidemic disease the mortality arising therefrom would be very serious. Both the district and urban authorities asked that an inspector of the Local Government Board should view the stream. In reply to this the clerk stated that he was informed by the department that the Board had during the last few years sanctioned the borrowing of large sums of money by the Birmingham Tame and Rea district drainage board to enable them to acquire further land to improve the effluent from their sewage farm, and the information in the Board's possession showed that the drainage board were aware of the necessity of carrying out the improvement. In reply it was stated that the amount of land the drainage board had at present for sewage treatment was utterly insufficient. At the inquiry before an inspection held in April, 1895, for leave to purchase 187 acres, the farm manager stated "that the sewage of 718 persons was at the present time dealt with on each acre of land, but the number ought not to exceed 400, and that the board then had 880 acres upon which to apply sewage and he should like the number increased to 1600." This would mean 720 acres more for sewage treatment than they then had. Some further correspondence was read in which the department replied that they were not prepared to direct an inquiry as suggested. It was decided to ask the Local Government Board to receive a deputation from the district council on the matter. Failing this it was intimated that the local Parliamentary representatives would be asked to bring the matter before the House of Commons.

Record Number of Summonses.

On April 14th the largest number of summonses on record was down for hearing at the Victoria courts. They reached the total of 178. Many of these were of minor importance, the mania for playing football in the public streets being responsible for 55. The preservation of order in the midst of a large town is indispensable to comfort and to progress; and the activity of the police towards this object is a laudable effort to promote good local government.

Inquests.

An inquest was lately held at the gaol on the body of a prisoner aged fifty-five whose death occurred under singular circumstances. The deceased persistently ate the peels of potatoes which had been cooked by steam. He was warned of the risk by another prisoner, but continued to indulge his taste for this exceptional kind of diet. Diarrhœa followed, then peritonitis and death. Previous slight chronic inflammation of the intestines was stated to have been the ground for the additional disease which was aggravated by the indigestible material.—The coroner has also held an inquest upon a child fourteen months old who endeavoured to swallow a piece of beef-steak, but failed in the attempt and died from asphyxia. Evidently information in the matter of feeding is further required among a number of people.

April 28th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Crisis at the Lying-in Hospital.

THE deadlock at this hospital still continues. It will be remembered that the bulk of the medical staff resigned in consequence of the determination of the committee to make the matron-midwife responsible for the treatment of all normal cases, which the latter body assert is in accordance with the rules of the charity, an interpretation controverted by the medical staff. A meeting of the subscribers was called to afford them an opportunity of putting their interpretation on the rules in dispute, at which the following resolution was carried by 22 votes to 2:—"That, whilst recognising the responsibility of the Medical Board through the honorary hospital medical officer on duty for the general supervision of all medical matters in connexion with the hospital, the subscribers regard the executive responsibility for the attendance upon normal cases as resting with the matron-midwife." Mr. J. K. Smith, in moving this resolution, remarked that "for a medical man not to be allowed to enter the wards with the object of supervising the antiseptic treatment was all nonsense"; while Mrs. H. Tate, a lady evidently endowed with much common sense, expressed her opinion that "no honorary medical officer could accept the position of being responsible for life and death in an institution to the wards of which he was denied access." Other speeches followed, after which the meeting dispersed leaving matters in a hopeless muddle. The absurdity of the situation was evidently felt by the committee in the fact of their meeting together immediately afterwards to put an interpretation on their own resolution, which reads as follows:—"That in the opinion of the committee the resolution (meaning that carried at the subscribers' meeting) is sufficient to confer upon the medical officer in charge the right of access to all wards for the purpose of carrying out the general supervision referred to." If this reading does not imply that the medical staff are to control the treatment of all cases, normal and otherwise, then the English language conveys no meaning whatever, yet when the medical staff, in reply to an invitation from the committee to allow themselves to be re-elected, say that they are agreeable, now that their responsibility for all hospital patients is established beyond shadow of doubt, will it be believed that the committee reply by saying that they "cannot agree to relieving the matron-midwife of the full responsibility of all normal cases, as they have complete confidence in her ability to tell whether a case is normal or otherwise"? It will not be wondered at that the staff, in reply, say that they cannot accept the position laid down by the committee, and that unless their responsibility for all cases is fully acknowledged (by the fact of the matron-midwife acting under their orders without reserve) they must definitely decline to offer themselves for re-election.

Death of Dr. John McGregor.

Dr. John McGregor, who some years ago enjoyed a lucrative practice in Everton, but latterly had been in failing health, was drowned in the Mersey on Tuesday week. Deceased was educated at Glasgow University, of which he was Doctor of Medicine, also possessing the Fellowship of the Royal College of Surgeons of Edinburgh. He was sixty-two years of age.

The New Northern Hospital.

At last a satisfactory stage has been reached in the progress of arrangements for rebuilding the Northern Hospital by the selection of the competition plans submitted by Messrs. Pennington, Son, and Harvey, architects, of London and Liverpool. The new hospital is designed to contain 200 beds, the existing one possessing only 157 beds. The site measures 11,000 yards. The style of architecture is that of English Renaissance plainly treated, and will be simple and neat rather than possessing external grandeur. The hospital, which will be a model of its kind, will include two large longitudinal pavilions three storeys high. The administrative block will form the centre with the principal entrance to the building which will be approached by a circular drive from the main street. It will contain a handsome entrance-hall and every convenience for the accommodation of the officials. A nurses' home to accommodate sixty nurses connected with the main corridor, giving access to all parts of the building, will be erected at the corner of Great Howard-street and Leeds-street. At the back of the main corridor will be a circular pavilion, also three storeys high, for the provision of operating and lecture theatres and the out-patients' department; there will be a separate entrance and exit to this part of the building. A feature of the new hospital will be the fitting up of three special wards with tanks for typhoid fever patients. At the rear will be placed the laundries, boiler-house, disinfecting-house, &c., with the mortuary and post-mortem room in another block. The building will be fireproof, whilst the heating, ventilating, and sanitary arrangements will be as perfect as possible. It is the intention of the committee to arrange to give the public an opportunity of inspecting the plans.

Glanders and the May Day Procession.

At the recent weekly meeting of the Health Committee the chairman said the May Day procession was postponed until it was quite certain there was no danger to be feared on account of glanders. The medical officer of health stated that the action taken in the matter was precautionary.

April 28th.

THE lectures at the National Hospital for the Paralysed and Epileptic, Queen-square, will be continued on Wednesdays at 3 o'clock, as before, but a larger number of members of the staff will take part in them. Dr. Gowers will begin on the 6th inst.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Bristol University College: an Appeal for £10,000.

THE Council of University College issued last week an urgent appeal for pecuniary assistance to the inhabitants of Bristol and the West of England. It is stated that since the last appeal was made, in 1887, a new medical wing has been built at a cost of £7590, an event followed by the complete incorporation of the medical school with the College, and an engineering wing was added at a cost of £5460. The council earnestly appeal for a capital sum of £10,000 to clear the College from debt and for an addition to the annual sustentation fund of £700, which would restore that fund to the £1200 subscribed in 1882, not less than which is required to meet the annual expenditure and to secure the Government grant. The council also emphasise the need of a permanent endowment, and suggest that wealthy citizens of Bristol and the West should associate their names, as in other colleges, with the endowment of professorships. The donations already promised for the capital fund amount to £5334, and to the sustentation fund about £100. At a recent meeting of the Technical Education Committee of the Bristol Corporation it was decided to recommend the Council to make a grant of £2000 to the funds now being raised on behalf of the College, to be conditional upon the £10,000 being obtained and on the acceptance of two representatives of the Town Council upon the governing body.

The Installation of the Prince of Wales as Chancellor of the University of Wales.

At a meeting of the University College of Wales, held in Cardiff last week, a communication was read from Sir Francis Knollys intimating that the Prince and Princess of Wales proposed to arrive in Aberystwith on June 25th, and, if agreeable, His Royal Highness suggested that his installation as Chancellor of the University should take place on the following day in that town. This date was considered most suitable, and it was decided that the installation should be conducted in a congregation of the authorities of the University. It has also been definitely arranged that the opening of the new residential hall for women in connexion with the University shall take place on the occasion of the forthcoming Royal visit, the Princess of Wales having graciously consented to perform the ceremony.

Lord Edmond Fitzmaurice on Vaccination.

At the meeting of the Bradford-on-Avon (Wiltshire) urban council on April 21st, when there was a strong expression in favour of vaccination, Lord Edmond Fitzmaurice said that he had not the smallest doubt that vaccination was one of the greatest scientific discoveries ever made. He looked upon the present agitation, and felt it his duty to say so, as having gone altogether beyond the question of compulsory vaccination; it was an attack upon vaccination itself, against the boards of guardians, and against the magistrates who enforced the law—in fact, in some places it had become almost a system of intimidation. It was time the working classes should have information on the other side placed before them.

Outbreak of Rabies at Weston, near Bath.

In consequence of an outbreak of rabies at Weston (near Bath) the market committee of Bath at a special meeting made an order for the muzzling of all dogs in the city; this came into force on April 20th last.

The Expenditure of the Bristol Public Health Department.

At the meeting of the Bristol sanitary authority, held on April 16th, it was stated that the expenditure of the Public Health Department for the half-year ended March, 1896, had been as follows: medical officer's department, £2237 14*s.* 2*d.*; hospital expenses, £1167; port sanitary account, £641; and Housing of the Working Classes Act, £908.

Conversazione of the Bristol University College.

The chairman and council of the Bristol University College gave a conversazione at the Victoria Rooms, Clifton, on April 20th. Scientific lectures and experiments were provided, and an opportunity was taken to impress upon the large number of citizens who attended that the College was greatly in need of increased financial help.

The Cheltenham Board of Guardians and Vaccination.

The Cheltenham board of guardians at a full board on April 23rd, after a discussion extending upwards of four hours, decided to rescind the resolution passed in 1894, so in future legal proceedings will be taken against all defaulters under the Vaccination Acts.

The new Infectious Diseases Hospital for Newport is to be opened in June.

Last week the sudden death occurred at his residence, "Sunny Lee," Weymouth, of Surgeon-Lieutenant-Colonel Richard William Hare, who was on the Retired List of the Army Medical Staff.

April 28th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Dr. A. F. Wood.

FRIENDS in the medical profession will hear with regret of the death of Dr. A. F. Wood, medical superintendent of the Edinburgh City Hospital. Dr. Wood died after four days' illness from acute pneumonia at the comparatively early age of forty-eight years. During his student days he showed a preference for the study of infectious diseases, and in 1878 was appointed house physician to the fever wards of the Old Infirmary, while in 1885 he was appointed by the town council to the post of superintendent of the City Hospital, which he held until his death. The funeral took place on the morning of April 24th and was attended by the Lord Provost and other members of the town council, as well as by a large number of the members of the medical faculty in Edinburgh and nurses from the city hospital. Dr. Wood had acquired great experience in the diagnosis and treatment of infectious diseases, and from his kindly, courteous, and obliging manner was much esteemed by the officials with whom he was associated and also by the friends of patients with whom he was brought in contact.

Edinburgh University General Council.

The statutory half-yearly meeting of the general council of Edinburgh University was held last week, the vice-chancellor, Sir William Muir, presiding. The report of the finance committee, presented by Mr. D. D. Beechan, S.S.C., expressed the satisfaction of the committee that the trustees of the late Earl of Moray had allotted to the University Court as a capital endowment fund for the promotion of original research in the University the munificent sum of £20,000. This sum, however, was by itself quite inadequate to equip the University for original research, and as there are no other funds at present at the disposal of the University Court by which to supplement it the committee suggest that a plan of coöperation with the Royal Colleges of Physicians and Surgeons of Edinburgh might be devised, by means of which the laboratories and endowments of the three bodies might be worked together instead of being in competition with one another. The committee stated their regret that the General University Fund showed no increase in capital, the figure being £70,000, practically the same as it was last year. They considered it unsatisfactory that so often money given to the University was appropriated by the donors to special purposes instead of being entrusted to the administration of the University Court. One of the members called attention to the falling off in the number of students at the University. He thought it very unfortunate that the professors were now entirely independent of fees, and thought there was some relation between this fact and the falling-off in numbers. He was glad to see that the committee recommended that there should be a stop put to the practice of allowing grants to the professors for laboratory and class expenses. Dr. Scott Dalgleish attributed the falling off in the number of students rather to the increased requirements in the preliminary examination.

Opening of Filters at Stirling Waterworks.

The four filters which have been constructed at Zouch in connexion with the Stirling waterworks were formally opened last week by Provost Kinross. The filters measure each 76 feet by 52 feet; there are also two clear-water basins 100 feet in diameter, the whole being made of enamelled brick. The works have cost upwards of £13,000.

Edinburgh Field Naturalists' Society.

At the concluding meeting of this society in Edinburgh last week Dr. Watson submitted a communication on recent observations by Dr. Cunningham, Professor of Physiology, Calcutta, on the nature of snake poison. Dr. Cunningham's investigations went to show that the lethal properties of cobra-venom were due to the presence in it of a single toxine of the nature of a ferment which altered the blood so as to make it unfit for the part it played in respiration, while the lethal properties of daboia venom were due to two toxines, not ferments, the one acting as a nerve irritant and the other by inducing septic alterations in the blood.

Death of Dr. Anderson, C.B.

The death took place on Sunday at Pitlochry of Dr. Anderson, C.B, retired Inspector-General of Her Majesty's Hospitals, at the age of eighty-one. He entered the army in 1838 and served sixteen years in the 82nd Foot, 10th Hussars, and 2nd Battalion of the Rifle Brigade in the Mediterranean, Canada, &c. He was appointed surgeon-general in 1854 and passed through the experiences of the Crimean War, having been present at the battles of Alma, Balaclava, and Inkerman, and at the Siege of Sebastopol. He was engaged in the war with China and subsequently served in India as principal medical officer in Bengal. When he returned home he received the appointment of principal medical officer of Netley Hospital. Dr. Anderson had the honour of being created a Knight of the Legion of Honour and a Companion of the Bath, and possessed the Crimean medal with four clasps, Turkish medal, and China medal and clasp.

St. Andrews University.

The Berry Scholarship in Natural Science has been awarded to Mr. Harry M. Kyle, M.A., B.Sc, Glasgow, and the Woodhall Fisheries Prize to Mr. Wm. Wallace, also of Glasgow.

Glasgow University.

The summer session opened on April 21st, and all the classes are now in full operation. The exact number or entrants cannot yet be stated, but as the results of the preliminary examination were much more favourable than in former years larger first-year classes are to be expected. Professor Simpson's health has so far improved that he is able to conduct the class in Forensic Medicine.—Dr. M. Charteris, Professor of Therapeutics, has been elected a Fellow of the Royal Society of Edinburgh.—The session at Anderson's College also opened on April 21st and at St. Mungo's College on April 24th.—Two new courses are announced at the Western Medical School, one on Regional Anatomy by Dr. Edington and one on Physiology by Dr. Ernest Thomson.—Dr. Pearson Munro, in consequence of ill-health, will not be able to conduct his class on Public Health in Anderson's College during the present session.

Lightburn Hospital, Lanarkshire.

The new hospital which has been erected for the purpose of dealing with cases of infectious diseases from the lower and middle ward districts of Lanarkshire was formally opened on April 23rd by Mr. Henry Taggart, convener of the joint committee. The hospital has been designed upon the most modern and improved principles. It contains accommodation for sixty beds, and the total cost, including the site, is estimated at £29,000. There is a complete installation of the electric light, and the hospital is provided with the Alliott-Paton patent Lyon's steam disinfecting apparatus. The opening ceremony took place in the presence of a number of representatives of the local health authorities and of the profession. At the lunch which followed the toast of "The Local Government Board for Scotland" was responded to by Dr. McLintock. The medical superintendent of the new hospital is Mr. Philp.

The Mild Weather.

As evidence of the mildness of the season Mr. Alex. Somerville, B.Sc., a well-known member of the Glasgow Naturalists' Society, announces that during the first week of April he collected fifty-eight species of wild plants in flower in the island of Arran.

A Medical Dispute.

A curious position has issued from a difference of opinion between two practitioners in a burgh in the west of Scotland. Dr. A. certified a case of enteric fever and sent the patient to the burgh hospital. Admittance, however, was refused, as Dr. B., who had charge of the hospital, diagnosed the case as one of meningitis. Dr. A., in no wise convinced of this view, sent for a consulting physician from Glasgow, who had no doubt the case was really one of enteric fever. Now Dr. A. maintains that the consultant's fee of 10 guineas is an expense to which he has been put by the burgh medical officer, and accordingly he claims that the town council ought to refund him this sum.

Presentation to a Medical Man.

The members of the ambulance class in connexion with the Possilpark district of Glasgow have presented Dr. J. S. Muir with a handsome dressing-case as an indication of their appreciation of his services as lecturer.

April 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Mourne Water Scheme for Belfast.

IT was in August, 1893, that the Belfast Water Act, which authorises this new scheme, received the Royal Assent. It is to supplement the present supply of water from Carrickfergus on one side of the city and Stoneyford on the other. At present the resources of the water commissioners give 11,000,000 gallons of water per day, and this, it is thought, will supply the city of Belfast under the usual circumstances until 1900. But the demand for water, owing to the remarkable growth of the city, is increasing every week, and the new Mourne supply will not be ready a day too soon. The Mourne gathering-ground contains over 9000 acres, and is at present drained by the two rivers Kilkeel and Annaling, which empty into the sea at the small towns of the same names in the southern part of county Down. Large reservoirs will be constructed in this area, which, if necessary for the city, can be doubled. At present the Commissioners are proceeding to construct the main aqueduct between the Kilkeel river and the Knockbracken service reservoir, which will be within a few miles of Belfast. This aqueduct will be 35 miles long, and while ultimately capable of taking the full product of the Mourne district—30 million gallons of water per day—the syphons will at first be laid with single pipes, which will carry 10 million gallons per day. Of the whole length of this aqueduct there will be 7 miles of tunnel, 16 miles of cut and cover, and 12 miles of syphon pipes, all 36 in. in diameter. The service reservoir at Knockbracken, about 5 miles from Belfast, the capacity of which will be 90 million gallons, is now in the process of construction (the contract is £35,000). From it the water will be conveyed under pressure by large mains to Belfast. The firm which is building the reservoir is also constructing 11¼ miles of the main aqueduct between the reservoir and a point about two miles from Ballynahinch. Of this aqueduct one-third will be tunnel (it will be the longest work of the kind in Ireland, about 3½ miles), another cut and cover, and a third cast-iron syphon pipes. At present the men are busy at this tunnel and the other parts of this portion of the aqueduct, and it is to cost £153,000. The pipes for the syphons are being made in Glasgow and will cost £21,000. The inlet ends of these pipes will be controlled by automatic valves, and by means of these the water will be immediately cut off in case of a breakage in any part of the syphon, thus reducing the chances of possible damage. Within the last few weeks the other end of the aqueduct—the Newcastle section—which begins at a place well known to tourists, the Bloody Bridge, and which covers about 11¼ miles in all, being made up of 7 miles syphon, 2 miles of cut and cover, and 2¼ miles of tunnel, the last-named passing under the highest of the Mourne range of mountains, Slieve Donard, was contracted for by a Belfast firm, the amount being £95,000. Work at this part will shortly begin, and in a few weeks about two-thirds of the whole length of the aqueduct, as well as the service reservoir, will be under construction. It will not be long before Belfast has a water-supply equal to its extraordinary size and rapidly increasing growth.

Queen's College, Belfast.

For some time it has been felt that the usual time of commencing the winter session at Queen's College, Belfast, has been too late; it has therefore been decided that next year, 1896-97, the medical classes will begin on Oct. 20th

Digitized by Google

and terminate on March 31st. The present summer session begins on May 1st. Two additional lecturers will shortly be appointed by the College council on Ophthalmology and Hygiene, as it is necessary that a course of lectures should be given next year in these subjects in order to qualify students for the examinations of the Royal University of Ireland.

Triennial Visitation at the Queen's College, Cork.

The triennial visitation was held on Tuesday last at the Queen's College, Cork, and, as had been expected, the Visitors present were Mr. Justice O'Brien (chairman), Dr. Grimshaw (President of the Royal College of Physicians of Ireland), and Sir W. Thornley Stoker (President of the Royal College of Surgeons in Ireland). The only appeals made to the Visitors were those of the Medical Students' Association, and had reference mainly to the anatomical department. The requests coming under that head were the following: that the dissecting-room should be open from nine o'clock to six o'clock instead of being closed at four o'clock as is the case at present; that the dissecting-room ought to be kept open during the summer session; that the number of demonstrators should be increased; that students who had already attended the requisite number of courses of anatomy should be allowed to dissect on paying a reduced fee; and that students similarly circumstanced should have the privilege of visiting the dissecting-room without being obliged to pay any fee. The Visitors considered that the dissecting-room ought to be kept open until six o'clock, and they referred back to the Council the question of having dissections included in a summer session. Sir W. Thornley Stoker was very strongly of opinion that it would be better to have one demonstrator who would devote his entire time to his duties rather than that the responsiblity should be divided between three or four, whose attention would probably be more or less absorbed by private practice in the city, and the Visitors decided accordingly. With regard to the payment of a reduced fee for dissections the Council had ruled that they were not in a position to interfere, but Mr. Justice O'Brien interpreted the statute of the College bearing on the subject differently, and the Visitors decided that whilst they considered a fee of £3 a moderate one for an ordinary course of dissections a student not requiring a certificate should be allowed to dissect on paying £2, plus the ordinary dissecting-room expenses. With reference to the admission to the dissecting-room of students who did not propose to take out a further course of dissections Sir W. Thornley Stoker stated that all teachers of anatomy are opposed to such a procedure as one calculated to interfere with the discipline of the dissecting-room, and he incidentally mentioned that such students are in Dublin called "navigators." The learned judge, when giving the decision of the Visitors, humourously said that they could give no assent to that kind of navigation. After some other questions had been considered Mr. Justice O'Brien stated that although the natural zeal for change and improvement of the students had brought under their notice matters not unworthy their consideration, still they were constrained to say as their opinion that they had revealed very few defects of any kind existing in the institution, and such as were revealed were capable of correction by them. Referring especially to the medical school of the College he said: "There can be no doubt that this College of the city of Cork retains its distinction as a great medical school. It has already furnished a very large number of professional men to different parts of the world, and I am very happy to say that in the opinion of my colleagues, who have, by zeal and acquirements, obtained such high distinction in both branches of the medical profession, this school of medicine and surgery in the city of Cork furnishes the means and opportunity of instruction which cannot be exceeded in any similar institution in any part of the United Kingdom."

ROME.

(FROM OUR OWN CORRESPONDENT.)

"Homicidal Explosion" in the Army.

WITHIN the last two years five cases of what Italian alienists classify as "homicidal explosion" have occurred in garrison life throughout the kingdom and a sixth was added to the number yesterday. This was at Palermo, where a private soldier named Fagioli of the 39th Battalion of Africa, in convalescence with several comrades in the regimental infirmary, suddenly seized a loaded rifle and discharged it at his corporal, who had just entered. Fortunately the intended victim's cap received the shot, no further injury being done; but before this was ascertained Fagioli's comrades fled in panic, followed by the corporal, while Fagioli barricaded himself in the room. There he remained, meeting all requests to open the door with the threat that he would shoot dead the first man who entered. Another door admitting to the room was then forced and Fagioli fired no fewer than twelve shots at the soldiers as they appeared at the doorway, but without inflicting any wound. He was then fired upon in turn, four bullets lodging in his head and spine, and thereafter conveyed to the hospital in a dying state. His motives can only be guessed at. All that is positively known of him is that he was a neurotic subject, of "cattivi precedenti" (bad record), and had undergone several terms of punishment for previous convictions. The Italian War Office has for some time been in conflict with medical authority as to how to view these cases and how to prevent their recurrence. Before the military court where they have been tried expert evidence by some of the first alienists of the kingdom has been given, clearly showing by every test, anthropometric and other, that the delinquents were, each and all, "moral imbeciles" whom a properly qualified inspecting authority would have, *ab initio*, excluded from the service. But no; the medical witnesses were respectfully listened to and their findings quietly ignored; the delinquents were found guilty of breach of discipline of the most aggravated kind and shot through the back in presence of their comrades. The sentence, followed by summary execution, has proved absolutely without deterrent effect, and for reasons amply set forth by the medical witnesses. The delinquents were in their view morally irresponsible from defective organisation physically and perverted development mentally—conditions easily ascertainable by inspection on their entering the ranks. But such inspection is a long way from being recognised as feasible or tolerated as admissible by the War Office. The conscription has undoubtedly many drawbacks as compared with the voluntary system of the British Isles, and one of them is the danger of accepting moral defect or criminal propensity as a bar to service. For, say the military men, as the eligible recruit, to avoid the conscription, will injure hand or foot to disqualify himself, still more easily would he commit a crime or pose as a "moral imbecile" for the same end. To recognise such "antecedents" as a bar to military service would put a premium on crime in Italy, already far too prone without such temptation to indulge in it. There is force in this argument, but not enough to meet the contention of the anthropological school. Why not begin ten or twelve years earlier in the young conscript's life? Why not take him at, or just before, entering school and subject him then and there to the tests, anthropometric and other, which science has reduced to such perfection? I need not recapitulate the proposals submitted by the Sub-Alpine and Lombard medical authorities particularly to the Education Office as worthy of being put in practice in the elementary schools throughout the kingdom. These have from time to time been published in THE LANCET and vindicated from the charge of "Utopianism" inconsiderately brought against them by the lay public. *Principiis obsta* holds good in the moral development as well as in the physical, and the whole future of Italian life, whether of the civilian or the soldier, is bound up in its due and vigilant observance. With "a murder every two hours" in civil life, and such wholesale outbursts of homicidal impulse as those of Misdea and other "moral imbeciles" admitted to service and to the use of lethal weapons, the wonder is that Italian population maintains the yearly average statistically noted, and that the annual loss of life in barracks and on a peace footing is not proportionally greater than that caused in a hostile country and on the stricken field.

April 26th.

THE seventh ordinary general meeting of the Sanitary Inspectors' Association (session 1895–96) will be held on Saturday, May 2nd, 1896, at 6 P.M., at Carpenters' Hall, Throgmorton-avenue, E.C.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

"Filled Cheese."

CONGRESS is engaged in the discussion of a Bill for the regulation of the manufacture of what is known as "filled cheese." This article, of which upwards of 12,000,000 lb. were manufactured last year, is an imitation of cream cheese and has been sold in the market as such. It is the result of the new method of separating the fatty substance from the new milk by centrifugal force and substituting other fats in the milk thus relieved of its natural fat. After taking leaf lard and subjecting it to a certain heat so that it becomes oil, and mixing a certain number of pounds of that with a hundred pounds of this milk, the subsequent process of manufacture is the same as that of other cheese. At different stages of the development of this industry various other fats and oils have been used, including oleo oil, margarine, cotton oil, and unmerchantable butter, as well as others still cheaper and of doubtful origin. In the process of manufacture the bulk of the milk is raised to the same temperature as in making ordinary cheese, while part of the milk and all of the lard are raised to a temperature of at least 200° F. The liability to use raw materials containing the germs of disease is about the same in making genuine cheese as in making filled cheese. The filled cheese is made and placed on the market without any brand or marking indicating its real nature. The sole object to be obtained by legislation is to prevent fraud by compelling the manufacturer to place on the package of filled cheese the name of the article.

The Vomito in Cuba.

According to recently published statements it appears that the greatest losses suffered by the Spanish army in Cuba are caused by the vomito, a disease which is a kind of yellow fever and which is deadly to the people and soldiers newly arrived on the island. From March 1st, 1895, to the present date the number of deaths in the military forces sent by Spain to suppress the Cuban revolution amounts to 3877. No less than 3190 of these deaths were caused by the terrible vomito. The rest were caused as follows: 886 men were killed on the battlefield, 119 died from wounds received while fighting, and 282 died from ordinary diseases. If this statement is correct the mortality did not exceed 4 per cent., which is much below that of the late war in this country and that of the French troops in Tonquin and Madagascar.

The Medical Corps of the Navy.

The Surgeon-General of the United States Navy has made some interesting statements in his annual report for 1895. When the corps is full it numbers 170 men, but it is very difficult to maintain a full corps. An examining board is constantly in session, but it fails to supply the needed members for two reasons—viz., first, because of the scarcity of applicants; and, secondly, because of the incompetency of those who do apply. Of the nineteen who applied last year but four passed a satisfactory examination, though the examination was not severe. These facts seem to prove that the naval service is more unpopular than other branches of the public service which have a medical corps. It is alleged by those who are familiar with the naval service that the position of the medical corps is humiliating as compared with that of other departments. The naval surgeon enters the service on a lower plane than does the army surgeon. For three years he is confined to the steerage and cannot mess with his profession. He can retire on a pension only after forty years of service, while the army surgeon may retire after thirty years of service. Finally, his rank is inferior to that of other officers and his promotion is correspondingly slow. A Bill is before Congress to improve the efficiency of the naval service, but the provisions in regard to the medical corps do not materially change its status.

Diphtheritic Palsies after the Use of Antitoxin.

The physician to the Hospital for Diphtheria in New York states that from time to time cases of general paralysis have followed diphtheria treated with antitoxin. In the last three months there have been two cases. One, an adult, had general weakness due to partial paralysis in all voluntary muscles so that she could not walk for three months; the other, a child, developed paralysis in some of the muscles of the lower limbs. In a third case paralysis of the muscles of the eye occurred. In a few paralysis of the palate or pharynx develops after the separation of the membrane. He states that more cases of paralysis occur now than formerly, but thinks this is due to the fact that a class of patients recover now who formerly died. He adds that patients who would recover without antitoxin will show less paralysis with antitoxin than without it.

Alien Paupers.

The State of New York has an agency devoted to the arrest of all persons who are paupers and their commitment temporarily in order to determine their proper settlement. When their homes are made out they are immediately sent there, whether in this country or abroad. Since the law went into effect 2632 permanently disabled paupers have been removed to European homes. It is estimated that if these people had been allowed to remain in this country, a charge upon the public, buildings would have to be erected for their shelter equal to the requirements of the poor of a population of 600,000, involving an outlay therefore of at least $500,000, and an ultimate expenditure for their maintenance and care of about $3,948,000. These removals have been openly conducted, and no well-founded complaints have been made by the relatives, guardians, friends, or European communities to which they were sent, and but three of those thus removed have reappeared in this State.

April 18th.

THE CONGRESS OF MEDICINE IN WIESBADEN.

THIS Congress was opened on April 8th, Professor BAÜMLER of Freiburg being in the chair. The members were welcomed by the President of the district on behalf of the Government and by the Mayor of Wiesbaden as the representative of the town.

In his presidential address Professor BAÜMLER said that the Congress held at Munich in April of last year must be regarded as a landmark in the history of these gatherings, inasmuch as the use of diphtheria antitoxin—the most remarkable therapeutical discovery of the age—was there discussed for the first time in detail by the most competent physicians of Germany. It must not be forgotten, however, that efforts to render the human body immune against the influence of morbific agents and to cut short pathological processes were of much earlier date, and, in fact, had their first successful application in the great discovery of Jenner. The present year being the centenary of Jenner's first successful vaccination the Congress was now about to honour the memory of this event so important in the history of medical progress.

The Prophylactic Influence of Vaccination.

Professor VON LEYDEN of Berlin then delivered an address on Vaccination, in which he said that the immense mortality from small-pox was never reduced by any of the measures that were adopted before the time of Jenner, even the most thorough isolation of the sufferers being powerless to prevent the spread of the infection. In the eighteenth century one-tenth of the entire mortality in England was due to small-pox, and in France it caused 300,000 deaths every year, while those who recovered from it were greatly disfigured and often rendered totally blind. Several palliatives were in use, the most noteworthy being the so-called variolation or inoculation of healthy persons with the contents of small-pox pustules. This practice was undoubtedly a step in the right direction, and up to the year 1758 more than 200,000 people were treated in this way, but it was ultimately abandoned altogether, as it was sometimes attended by serious results and inevitably tended to maintain and propagate the disease. Jenner, then, was the first, not only to prove that cow-pox acts as an antitoxin against small-pox, but also that the small-pox virus becomes weakened or strengthened by inoculation on and from different species of animals—a fact which has in our own day been confirmed by Pasteur. Jenner's opinion that a single vaccination would confer life-long protection was not borne out by experience, and it was now known that the operation must be repeated after the lapse of ten years. Modern improvements in the methods of vaccinating and revaccinating, and the exclusive use of animal lymph, which is the rule in Germany, ought to disarm the hostility of the

Digitized by Google

anti-vaccinationists. Jenner had to struggle against prejudice and opposition, and even now there are people who declare that vaccination is useless and injurious; but we all know that Jenner's work was a blessing to humanity and has been the starting-point of all the modern discoverers, of Pasteur, Koch, and Behring.

Antipyretic Drugs.

Professor KAST (Breslau) said that recent researches had shown that in infectious diseases the danger to the patient was due not so much to the elevation of temperature as to the direct effects of the specific virus. There are even reasons for believing that pyrexia may possibly be a natural remedy provided by nature against the toxines. We now try to destroy the toxines by applying their specific antidote or antitoxin. No antipyretic drugs have any specific action against the toxines except quinine, which is in reality a specific antidote against malaria. Antipyretic drugs, however, have their proper place in therapeutics and cannot be dispensed with on account of their power of mitigating several grave symptoms, especially those which involve the nervous system, such, for instance, as insomnia. In these circumstances Professor Kast considers antipyrin to be the best remedy.

Professor BINZ, speaking as a pharmacologist, discussed some of the most commonly employed antipyretic drugs, such as quinine, antipyrin, salicylic acid, and thallin.

Professor JAKSCH (Prague) agreed with Professor Kast that the principal value of these drugs consisted in their tranquillising influence.

Dr. DETTWEILER (Königstein) recommended their use in phthisis when want of appetite caused by the fever makes the nutrition of the patient difficult.

Rheumatoid Diseases.

Professor GERHARDT (Berlin) directed the attention of the meeting to a group of diseases which are clearly distinct from acute rheumatic fever, but are nevertheless characterised or attended by morbid alterations in the joints, and include scarlet fever, diphtheria, typhoid fever, influenza, syphilis, gonorrhœa, &c. He specially mentioned acute tonsillitis (angina lacunaris), in which there often is an affection of the joints very like acute rheumatic fever. All these complications he proposed to classify as rheumatoid.

APRIL 9TH.

Immunisation against Cholera and Typhoid Fever.

Professor GRUBER (Vienna) described his recent experiments on the production of immunity against cholera and typhoid fever. He has found that the serum of guinea-pigs immunised by the inoculation of living or dead cultures of the bacilli of cholera or typhoid fever is able to immunise other animals. If cultures of bacteria are mixed with this immunised serum these bacteria become altered in a very remarkable way, losing their mobility and collecting in masses. This state is called by Professor Gruber agglutination, and it is produced by cholera or typhoid fever serum not only with the bacteria of these diseases but also with a number of other bacteria. At the normal temperature the serum not only agglutinates the bacteria, but destroys them; if the serum is raised to 60° C. (140° F.) it loses its bactericidal quality and only retains the agglutinating one, but when a drop of fresh serum is added the bactericidal quality at once reappears. According to Professor Gruber immunisation assists the action of the natural bactericidal substances which are contained in the serum (the alexines of Dr. Buchner). He considers that this action is efficient against any kind of bacteria, and he opposes the views of Professor Koch and his school, who maintain that the serum of an immunised animal acts only against one specific kind of bacteria, so that, for instance, cholera serum is effective only against the bacillus of cholera.

In the ensuing discussion Professor PFEIFFER (Berlin), chief of Professor Koch's laboratory, stoutly upheld his opinion that a specific bacterium can only be destroyed by a specific antitoxin. The agglutination described by Professor Gruber is merely a consequence of the degenerating influence of a specific antitoxin on specific bacteria.

Dr. BLACHSTEIN argued that the so-called active and latent virulence of bacteria must be better distinguished. The latter varies according to the nature of the nutrient medium in which the bacteria are growing.

The Heart and the Vaso-motor Apparatus in Infectious Diseases.

Dr. PAESSLER (Leipzig) read a paper on the Action of the Heart and the Vaso-motor Apparatus in Infectious Diseases. He has found, together with Professor Romberg, that the lowering of the blood-pressure in grave cases is due to a paralysis of the vaso-motor nerves consequent on a paralysis of the centre in the medulla oblongata, whilst the cardiac power is not obviously damaged.

Paracentesis of the Spinal Canal.

Professor LENHARTZ (Leipzig) in a communication on Surgical Puncture of the Spinal Canal said that he considered it to be an operation of great diagnostic and therapeutic value. As a means of diagnosis it enables us to make a bacteriological and microscopical examination of the fluid contained in the theca and to ascertain its specific gravity. The operation has never had any unfavourable influence on the patient's health, and has been successfully performed in acute serous meningitis, in chronic tuberculous meningitis, in the so-called epidemic cerebro-spinal meningitis, and in hydrocephalus.

Dr. KRÖNIG, Dr. EWALD, Dr. GOLDSCHEIDER (Berlin), and Professor QUINCKE (Kiel) agreed with Professor Lenhartz that the operation might be of practical utility if cautiously employed. It was described in THE LANCET about a year ago.[1]

Absorption of Ferruginous Compounds.

Professor QUINCKE (Kiel) described his recent experiments on the absorption and excretion of ferruginous compounds by the organism, a question already discussed in detail at last year's meeting of the Congress in Munich.[2] He has been able to prove that in guinea-pigs and rats iron is taken up by the duodenum, jejunum, ileum, and cæcum through the epithelial cells. The absorption of iron is thus very like that of fat.

Dr. SIEGFRIED (Rippoldsau) pointed out that these experiments were a definite proof that iron is an assimilable remedy, a clinical fact long known to all practitioners. He hoped that the contrary views expressed at the last Congress were now finally disposed of. He then referred to the successful treatment of chlorosis by means of ferruginous preparations combined with residence in mountainous localities.

(To be continued.)

Medical News.

CAMBRIDGE UNIVERSITY.—The following candidates have satisfied the examiners in both parts of the examination of Sanitary Science:—

Henry William Beach, Joseph John Guthrie Blandford, George Fletcher Collins, Jonathan Nield Cook, Frederick James Crawford, James Entrican, Alfred Ernest Evans, Charles Arthur Kent, Arthur Martin Mitchell, Frederick William Sell, Arthur John Sharp, Henry Thomson, William Booker Vance, and Charles Louis Williams.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—In the first examination for the degree of M.B. the following candidates have passed in the subjects indicated:—

Chemistry with Chemical Physics, and Botany with Medical Botany.—Alfred Thornhill Greenhill, College of Medicine, Newcastle-upon-Tyne.

Chemistry with Chemical Physics.—John Harris, B.A., Sydney University; Herbert Robert Cambridge Newman, Bristol Medical School; George Norman, M.R.C.S., L.R.C.P., Westminster Hospital; Vaughan Pendred, M.R.C.S., L.R.C.P., Guy's Hospital; George Woodyatt Procter and Robert Alfred Wilson, College of Medicine, Newcastle-upon-Tyne; and Maurice Frederick Squire, M.R.C.S., L.R.C.P., St. Mary's Hospital.

Elementary Anatomy and Physiology.—John Henry Martin and Fred Sutton, College of Medicine, Newcastle-upon-Tyne.

In the first examination for the degree of M.B. under the new regulations the following candidates have passed in the subjects indicated:—

Elementary Anatomy and Biology, Chemistry, and Physics.—Honours: First Class—Richard Henry Dix, College of Medicine, Newcastle-upon-Tyne. Second Class—Ernest Frederick Wharton Bywater, Mason College, Birmingham; and Fred Stuart, College of Medicine, Newcastle-upon-Tyne. Pass List: Ernest Bertram Appleby, Harry Armstrong, Solomon Cross, Maurice Jacobs, and Edward Norman Threlfall, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy, Chemistry, and Physics.—Frederick Day Welch, London Hospital.

Anatomy and Biology.—Arthur Hugh Bunting, Hubert Wolstenholme, Horan, John Robert Mitchell, John Ernest Sidgwick, and David

Henderson Weir, College of Medicine, Newcastle-upon-Tyne; and Margaret Joyce, London School of Medicine for Women.

Chemistry and Physics.—Alan Ayre-Smith and Edward Hovendon Burleigh Barlow, Guy's Hospital; Percy Francis Alderson, Middlesex Hospital; Laurence James Blandford, Clifford Harold Brookes, Sydney John Snow Cooke, Charles Henry Gibson, Arthur Hines, Hugh Robert Kendal, Eliot Swainston, and John Charles Velenski, College of Medicine, Newcastle-upon-Tyne; Arthur Russell Baker and Robert Walker, St. Bartholomew's Hospital; Edleston Harvey Cooke, St. Thomas's Hospital; Selina FitzHerbert Fox and Claudia Anita Prout Rowse, London School of Medicine for Women; Robert James Pearson, Edinburgh School of Medicine; and Thomas Basil Rhodes, Mason College, Birmingham.

Chemistry.—Wm. Henry Isaacs Bathurst, King's College Hospital.

Anatomy.—Harold Robert Dacre Spitta, St. George's Hospital; and Frank Wheler Sime, Guy's Hospital.

In the second examination for the degree of M.B., the following candidates have passed in the subjects indicated:—

Anatomy, Physiology, and Materia Medica.—Honours—Second Class: Maurice Frederick Squire, M.R.C.S., L.R.C.P., St. Mary's Hospital; Herbert Robert Cambridge Newman, Bristol Medical School; Robert Lowis Routledge, College of Medicine, Newcastle-upon-Tyne; Vaughan Pendred, M.R.C.S., L.R.C.P., Guy's Hospital; and James McConnell and Lawrence Fielder Hemmans, College of Medicine, Newcastle-upon-Tyne. Pass List: John Thomson Bell, Thomas Ponsford Cann, Leopold Stanley Davison, Henry Edward Davison, Henry Adamson Fielden, Thomas Harold Gibbs, Douglas Hethcote, Robert Atkinson Morland, Harold Turner Newton, Claud Maxwell Pennefather, Maurice Dale Wood, Allan Mackie Garnock Walker, and Thomas Blandford Watson, College of Medicine, Newcastle-upon-Tyne; Wm. Henry Isaacs Bathurst, and Ernest Castleigh Bailey, King's College Hospital; William James Codrington, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Francis Gerrard Hamilton Cooke, and Thomas Stokoe Elliot, Cooke's School of Anatomy; Samual Percy Johnson, Mason College, Birmingham; and George Norman, M.R.C.S., L.R.C.P., Westminster Hospital.

Anatomy only.—Charles Augustus Vogwell, College of Medicine, Newcastle-upon-Tyne.

UNIVERSITY OF EDINBURGH.—The following candidates have passed the examinations indicated below:—

Second Professional Examination for the Degrees of M.B. and C.M. (Old Ordinance).—F. T. H. Adamson, H. L. Apthorp, A. B. Blair, E. L. Borthwick, C. W. Breeks, F. W. Broadbent, D. A. Cameron, M. N. Choudhuri, A. W. G. Clark, D. E. Dickson, J. H. S. B. Douglas, D. L. Fisher, R. M. Gibson, W. H. Goldie, T. P. Greenwood, James Grieve, F. S. Harper, A. G. Hayden, Robert Irvine, A. L. de Jager, Leslie Kingsford, J. S. Lyle, B. A. M'Gregor, J. M. Macgregor, R. F. Mudie, B. N. Mullan, Sarat Mullick, W. D. Osler, D. J. Peirson, G. M'D. Pratt, Oswald Raitt, C. R. Scott, D. C. Sethna, T. B. Schoolbread, E. L. Starmer, J. F. Strickland, J. T. Titterton, W. A. C. Ussher, Henry Waters, G. F. Waterston, and M. B. Wright.

Second Professional Examination for the Degrees of M.B. and Ch.B. (New Ordinance).—John Alcindor, A. J. T. Allan, James Allison, A. S. Allum, J. R. Anderson, H. L. S. D. Belasco, William Bell, J. M. Bowie, Stanley Branch (with distinction), C. S. Brebner, R. N. Brebner, H. H. Broome, James Burnet, M.A., John Cameron (with distinction), J. A. Craig, William Craig, Robert Cumming, J. M. Cuthbert, L. J. M. Deas, George Dick, R. J. Dick, W. H. Dickinson, J. B. Dods, F. H. Dommisse, W. S. Eaton, Duncan Forbes, A. D. Fordyce, A. T. Galleton, Robert Gibson, J. D. Gilfillan, Andrew Gilmour, Alexander Goodall, A. M. Green, W. G. Heath, T. E. Hincks, H. T. Holland (with distinction), C. A. B. Horsford, B. S. Hyalop, W. J. Jones, A. H. Keun, G. E. J. King, G. de Lebat, B. W. Lewis, George Lyon (with distinction), J. C. M'Conaghey, Edward M'Culloch, W. C. M'Donald, John M'Gibbon, J. W. M'Intosh, D. V. M'Intyre, M.A., W. E. M'Kechnie, R. W. M'Kenna, J. W. Mackenzie, T. D. M'Laren, J. W. Mathewson, J. A. Murray, B.Sc., J. H. P. Paton, W. M. Paul, M.A., C. M. Pearson, G. B. Pemberton, A. H. Pirie, Robert Pugh, J. A. Raeburn, H. S. Roberts, A. A. Robinson, A. C. Sandstein (with distinction), R. F. M'N. Scott (with distinction), J. A. C. Smith, Ward Smith, G. H. Stewart, Henry Taylor, David Wardrop, W. C. Wilson, and G. J. Young.

Anatomy and Physiology of the Second Professional Examination.—W. M. Barker, Robert Bruce, Robert Crawford, E. F. Cyriax, C. L. Dunn, R. W. T. Ewart, F. B Feast, J. M. Fraser, H. E. Gibbs, A. A. Gunn, W. E. Hutchison, P. L. M'All, A. C. M'Gilchrist, Robina M'Gregor, G. A. Mackay, William M'Kay, M. B. Marshall, T. R. Matthews, W. P. Meldrum, Faith Philpot-Crowther, J. H. Rhodes, Edgar Somerville, W. B. Tellet, R. le Verley, Henry Wade, and D. C. Wallace.

Third Professional Examination for the Degrees of M.B. and Ch.B.—B. R. Aldren, V. G. Alexander, T. R. W. Armour, E. P. Baumann, Thomas Biggam, R. B. Black, H. F. Boland, William Burns, M.A., R. C. Cunningham, David Clow, C. M. Cooper (with distinction), L. W. Davies, James Donaldson, G. L. Findlay, James Forrest, J. S. Fraser, George Gatenby, Andrew Gibson, William Hamilton (with distinction), Rowland Hill, G. B. Hollings, Patrick Kinmont, A. B. MacCarthy, T. J. T. M'Hattie, J. L. M'Innes, John Malcolm, William Martin, J. D. S. Milln, F. W. More, R. G. Riddel, J. D. Slight, M.A., W. M. A. Smith, W. R. Somerset, J. W. Struthers, G. A. Vincent, W. M. Wilson, and A. G. Worrall.

Robert Sproule has passed the first professional examination in addition to the candidates whose names have already been published.

UNIVERSITY OF ABERDEEN.—WINTER SESSION 1895-96.—University Gold Medals have been gained by the following students:—

Fife Jamieson Memorial Gold Medal in Anatomy, John J. R. Macleod; Keith Gold Medal for Systematic and Clinical Surgery, Robert Bruce, M.A.; Shepherd Memorial Gold Medal for Systematic and Practical Surgery, Henry J. M'Grigor; Matthews Duncan Gold Medal in Obstetrics, C. A. Barclay Laing, M.A.; and Dr. James Anderson Gold Medal in Clinical Medicine, William Hunter.

The following candidates have passed the examinations for the degrees indicated below:—

Degree of B.Sc.—William Shepherd Laverock, M.A., Aberdeen (with highest honours).

Degree of M.D.—William Henry Clark, M.B., C.M., Aberdeen; David Macdonald Davidson, M.B., C.M., Surgeon-Captain, Indian Medical Service; Ashley Watson Mackintosh, M.A., M.B., C.M., London (with highest honours); Cyril James Mansfield, M.B., C.M., Surgeon, R.N., H.M.S. *Anson*; Arthur Henry Rideal, M.B., C.M., Brooks's Bar, Manchester; William Ross, M.B., C.M., Leeds; James Wilson, M.A., M.B., C.M., Wilts County Asylum, Devizes (worthy of commendation); and John Thomson Wilson, M.B., C.M., Inverclyde, Bothwell (under the New Ordinances; worthy of commendation).

Degrees of M.B. and C.M.—Clifford Thiselton Bell, Aberdeen; George Brown, Aberdeen; David Buchan, Aberdeen; William John Byres, M.A., Aberdeen; Robert Fraser Campbell, Wark-on-Tyne, Northumberland; George Chalmers, Huntly; Clarence Isidore Ellis, Mannamead, Plymouth; William Archer Irvine Fortescue, Kingcausie, Maryculter, near Aberdeen; Andrew Thomas Gage, M.A., B.Sc., Aberdeen; John Lyall Grant Gillanders, London; James Leslie Gordon, Old Aberdeen; John A. Alex. Gordon, M.A., Gordonville, Dingwall; Patrick Grant, M.A., Grantown-on-Spey; Thomas Harper, Netherton, Insch, Aberdeenshire; Francis Irvine, Aberdeen; John Grant Jones, Glenlossie, Elgin; Charles Alex. Barclay Laing, M.A., Pitsligo, Fraserburgh; James Alexander Mearns, Kinellar, near Aberdeen; James Adam Milne, M.A., Aberdeen; Hugh Osborne, Kirkcudbright; Alexander Presslie, Aberdeen; Archibald Ramsay, Stonehaven; Andrew Richardson, Aberlour-on-Spey; George Brebner Scott, Peterculter, Aberdeenshire; Henry Sinclair, Ashfield, Cults; James Ramsay Smith, M.A., Ellon; George Stephen, Ellon; George Irvine Thompson Stewart, M.A., Banchory, near Aberdeen; Andrew Thomson, Elgin; Andrew George Anderson Thomson, M.A., Keith (with honourable distinction); Frederick Mayfield Tindall, Fraserburgh; Alexander Watt, Stonehaven; Thomas Duncan Webster, Old Aberdeen; Charles Frederick Weinman, Colombo, Ceylon; and James Strachan Wilson, Aberdeen.

John Geddes Pirie, Buckie, has passed the examinations for the degrees of M.B. and C.M., but will not graduate until he has attained the necessary age.

Degrees of M.B. and Ch.B. (under the New Regulations).—Peter Mackessack, B.Sc., Kinloss, Forres.

The Diploma in Public Health has been conferred on William E. G. Duthie, M.A., M.B., C.M., Woodside, Aberdeen; Alex. Robb, M.A., M.B., C.M., Peterhead (with credit); and Charles L. Swaine, M.D., Indian Medical Service, Madras.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Drs. Köppen, Thierfelder, and Nasse have been promoted to Extraordinary Professorships of Psychiatrics, Physiological Chemistry, and Surgery respectively.—Dr. Oestreich has been recognised as *privat-docent* in Pathological Anatomy.—*Marburg:* Dr. A. Barth has been promoted to an Extraordinary Professorship of Surgery.—*Rostock:* Dr. Barfurth of Dorpat has been appointed to the Professorship of Anatomy and to the Directorship of the Anatomical Institute in succession to the late Professor von Brunn.—*Strassburg:* Dr. J. Klein has been recognised as *privat-docent* in Midwifery and Gynæcology.—*Toulouse:* Drs. Pénières, Rémond, Saint-Ange and Broemer, have been appointed to the chairs of External Pathology, Clinical Mental Diseases, Therapeutics, and Materia Medica respectively.

LEEDS GENERAL INFIRMARY.—The new operating department of the Leeds General Infirmary will be erected on the site of the structure which it will supersede, the available area being about 52 ft. by 58 ft., and it will consist of nine rooms, with a general entrance lobby which opens on to the landing of the principal staircase. According to the designs of the architect, Mr. W. H. Thorp of Leeds, these rooms include two operating theatres, each about 20 ft. by 23 ft., communicating with one another through the entrance lobby and also through the instrument room, which measures about 14 ft. by 16 ft. and lies between them, having two doors opening one into each theatre. Two anæsthetic rooms, each about 12 ft. by 16 ft., are arranged one for each theatre, and they lead also each into a separate waiting-room which opens on to the landing of the staircase, so that there are three doorways giving access to the stairs. The remainder of the nine rooms are the recovery-room and the surgeon's room. The division walls will be brick, and the woodwork chiefly teak. The floors of the two theatres and the instrument room will be terrazzo, and the walls will be lined from floor to ceiling with opaline, a substance which has been used in France for this purpose, but not hitherto in England; it is said to be composed of an exclusively mineral enamel in a completely vitrified state, and to be unaffected by acids, frost, or damp. The lining of these three rooms is estimated to cost about £360. They will have roof lights in addition to front and side windows, and the remaining portions of the roof will be concrete. The ventilation will be on the plenum or propulsion system, and the lighting will be by electricity. The entire cost will probably be from £4000 to £5000.

Digitized by Google

THE treasurer of Guy's Hospital has received a donation of 100 guineas towards the special re-endowment fund from the Liebig's Extract of Meat Company, Limited.

"NATURE" of Thursday next, May 7th, will contain, as an addition to the Science Worthies Series, a Life and an Appreciation of Sir Joseph Lister, P.R.S. The latter will be by Professor Tillmanns of Leipzig. A photogravure portrait of Sir Joseph Lister will accompany the articles as a supplement.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The William Tite Scholarship has been awarded to Mr. C. F. Selous; the Peacock Scholarship to Mr. J. Gaff; the Musgrove Scholarship, Second Tenure and First College Prize, to Mr. H. E. Hewitt; the Mead Medal for Practical Medicine to Mr. A. W. Sikes; the Cheselden Medal for Surgery and Surgical Anatomy to Mr. J. P. Scatchard; and the Treasurer's Gold Medal to Mr. J. P. Scatchard.

FOOTBALL CASUALTIES.—On the 25th ult., in a Cup-tie match, Kensal St. Mary's against the Old Antonians, a player fractured the fibula of his left leg.—On the same day, in a game on Holbeck Moor, Leeds, a player sustained a fracture of his leg, and was taken to the General Infirmary. A Cumberland player, aged twenty-four years (a forward), while playing for Cumberland at Workington, in the county championship match against Yorkshire, was injured by a blow on the back of the head behind the right ear. He did not feel any immediate effect and continued playing, but subsequently was admitted to the Cumberland Infirmary, where he underwent two operations. He so far recovered as to be able to leave the infirmary, but had a relapse, and died at home, in Carlisle, on Sunday last.

THE LONDON LOCK HOSPITAL AND RESCUE HOME.—The annual report of the London Lock Hospital and Rescue Home for 1895 is of an encouraging character, although the state of the finances does not yet permit the reopening of two wards belonging to the hospital and containing about 40 beds which have now been unoccupied for some years. On Dec. 31st, 1894, there were 41 inmates in the Home, and 66 were admitted during 1895. The matron has no difficulty in obtaining situations for the girls who have passed through the Home. The quality of the work done in the laundry gave general satisfaction, and the amount thereby earned was £1120. There were 709 admissions into the hospital during the year, some of them being very young girls and others being married women. The indebtedness of the charity was £5119 on Dec. 31st, 1893, but this large deficit has now been reduced to £302.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The forty-seventh annual meeting of the governors of the Wolverhampton and Staffordshire General Hospital was held at the Bell Medical Library on March 10th. The report stated that the number of in-patients treated during the past year has been 2078 (of these 946 were medical and 1132 were surgical cases), and the number of out-patients has been 14,742. The ordinary income for the past year has amounted to £7544 10*s.* 9*d.*, being an increase of £169 10*s.*, as compared with the previous year. The Hospital Saturday collections have amounted to £3320 17*s.* 5*d.*, being the largest sum collected since the inauguration of the movement twenty-two years ago, but the Hospital Sunday collections have decreased by £63 5*s.* 8*d.* The total expenditure for the year has amounted to £8107 4*s.* 2*d.*, as compared with £8082 5*s.* 11*d.* in the previous year.

THE MEDICAL SOCIETY OF LONDON.—The election of the officers and council for the session commencing October, 1896, will take place on Monday, May 11th. The following are the names of Fellows nominated for office by the council:—President: Reginald Harrison. Vice-Presidents: John C. Thorowgood, M.D., Charles B. Lockwood, Constantine Holman, M.D., and A. Pearce Gould. Treasurer: David H. Goodsall. Librarian: William Henry Allchin, M.D. Honorary Secretaries: George R. Turner and Robert Maguire, M.D. Honorary Secretary for Foreign Correspondence: Alban H. G. Doran. Council: John Anderson, M.D., C.I.E., Howard Barrett, William H. Battle, Frederick L. Benham, M.D., Robert L. Bowles, M.D., J. Mitchell Bruce, M.D., Henry H. Clutton, Sidney Coupland, M.D., Sir James Crichton-Browne, M.D., F.R.S., Sir Dyce Duckworth, M.D., F. de Havilland Hall, M.D., Henry E. Juler, Norman Kerr, M.D., Jonathan F. C. H. Macready, Edward J. Nix, M.D., James W. J. Oswald, M.D., Heinrich Port, M.D., Amand Routh, M.D., Joseph White, and Arthur K. Willis.

MESSRS. DUNCAN, FLOCKHART AND CO. of Edinburgh have opened a branch establishment at 38, Snow-hill, London, E.C.

PRESENTATIONS.—Mr. J. Leslie Callaghan has been presented with a gold watch (suitably inscribed) and an illuminated address as a token of respect and esteem from his patients and friends on his leaving Colyton. He was also presented with a barometer, with a suitable inscription on a silver plate, by the members of the Colyton Social Club in recognition of his services as president.—On April 22nd a handsome black marble timepiece was presented to Dr. H. Rogers-Tillstone by his ambulance and nursing classes, Clevedon, as a mark of their esteem.—Dr. H. J. Mackay of Devizes has been presented by the ladies attending the "First Aid" and "Nursing" classes, which he has recently given in connexion with the St. John Ambulance Association, with a handsome marble clock.—On the 18th ult. Dr. F. W. E. Hutchison, lately assistant to Mr. E. J. Parrott of Hayes, Middlesex, was presented with a gold medal by the inhabitants of that place.—Mr. John S. Forrest, L.R.C.P. Edin., L.F.P.S. Glasg., has been the recipient of a silver hunting flask from the members of the Warkworth Ambulance Classes as a token of appreciation of services rendered to them.

THE DIFFUSION OF SMALL-POX.—The records of the past two weeks serve to indicate that the disease is slowly spreading itself in the provinces. In London it remains quiescent at a low figure, the cases from week to week being now few in number. But attacks are occurring near at hand. At Guildford, after a scare created by the notification of an alleged case of small-pox in a tramp from Gloucester, which turned out to be in reality scarlet fever, a case of the graver disease has been found in the person of a tramp hailing from Westminster. Some stir resulted in the town, nurses were obtained, the case was isolated, and the authorities of Leatherhead were informed, the man having previously passed through that town. The patient died on Saturday last and was buried on the following Monday. Four cases have occurred at High Wycombe, the patients being workers in a paper mill who were brought into contact with rags stated to have come from Gloucester. The town council have been busy in the matter of a temporary hospital near the place, to the great dissatisfaction of the residents around the site of the structure. The guardians have by the casting vote of the chairman determined to enforce the Vaccination Acts, which have been in abeyance for three years, a large number of children having thus escaped vaccination. It is stated that no system of notification is in force in the town. High Wycombe would seem to be far behind the times in the direction of preparation for the stamping out of infectious disease. Much concern is felt lest there should be a widespread epidemic of small-pox there. A case of small-pox was recorded in Malmesbury last week, the victim having the disease mildly, after having been to and fro between Gloucester and Westport several times. The town was shortly after notification of the case placarded with posters urging people to seek vaccination and revaccination. At Gloucester the official returns for the week ended on Thursday, April 23rd, showed that in the week the new cases of small-pox coming to the knowledge of the town council were 168 in number, as against 211 and 201 in the preceding two weeks—a decided fall. These cases brought the grand total during the epidemic to 1470. The cases discharged from hospital in the week in question were 18 in number, the deaths in hospital being also 18, with other 25 deaths registered in the town; and 278 patients were left under treatment in the hospitals. It is satisfactory to have thus to record a decline in the manifestations of the disease, and this especially, seeing that the more insanitary parts of the city are now to some extent being invaded. Still, the disease does not seem to be on this account getting any stronger hold on the place, but rather the reverse. To the end of last week it is computed that 25,000 persons have been vaccinated during the epidemic, and it is stated that a large number of these have been vaccinated by one medical practitioner. During last week the vaccinations and revaccinations carried out at the public charge by the public vaccinators numbered 2231, a falling off from the total of the previous week. The authorities have not slackened their activity, however, in any way, and have had the advantage during last week and part of the present week of conference with Dr. Sweeting, from

Digitized by Google

the Medical Department of the Local Government Board, that Board having sent him down at the request of the guardians. Much practical good seems to have resulted from his visit, as the problem of how best to secure the vaccination of the great number of residents still to be operated on seems to have been solved. The town council were not slow to assure the guardians that much more needed to be done than they were doing in this direction, and now the city has been mapped out in some dozen districts for house-to-house visitation purposes and vaccinators to a like number have been appointed for the better securing of domiciliary vaccination. Dr. Sweeting, it would seem, held conferences with committees and with the whole body of the guardians, and vaccination officers as well as medical men have been now for the past few days more busy than ever, the responsible duty of supervision being entrusted to Dr. Bond, the medical officer of the neighbouring combined sanitary district of Gloucestershire. We are glad that the guardians have been so fortunate as to obtain the services of such an experienced medical officer of health to superintend the heavy work still to be done. Dr. Sweeting in his last interview with the guardians pointed to the presence of 3000 unvaccinated helpless children in the city still, and it was for the protection of these innocents that extra help must speedily be forthcoming if they were to be saved from becoming victims to the dread scourge which was working such havock among the unprotected young. There seems a marked disposition on the part of the guardians to enforce the Vaccination Acts. The Ambulance Committee of the Metropolitan Asylums Board have complied with the request of the town council of Gloucester that they should allow Dr. Brooke of the Thames Ambulance Service to proceed to Gloucester to take charge of the hospital arrangements. The cost to Gloucester of the epidemic is estimated at some £12,000, and is to be met by a half-yearly rate of 9*d*. in the pound. Dr. Coupland is still carrying on his investigations on behalf of the Royal Commission on Vaccination. It is stated that no recently revaccinated person has contracted small-pox. Seeing that the Commission has so long delayed its report, it is as well that it should be in a position to add the weighty practical evidence of Gloucester to its records. The only danger is lest the rush for vaccination such as has been going on should have led to operations of an inferior class, thus casting discredit on vaccination by reason of only partial protection against small-pox being conferred. This is always a danger to be feared when public stations and other places are flooded by clamouring applicants for a too long delayed prophylactic measure. At Coventry the stations are now daily crowded with persons seeking vaccination for themselves and their children, calf lymph being exclusively used. Many private vaccinations are also being performed. The guardians of Scarborough also have resolved to enforce the Acts. At Neath a family of eight persons has been attacked by small-pox, and two brothers who strenuously refused to be vaccinated have died from small-pox. At Swansea a man has been summoned for concealing a second case of small-pox in his lodging-house, he having stated to daily inquiries that no further attack had followed the initial case. Last Saturday there were 18 cases in the hospital at Swansea, and three additional cases occurred last week, leaving 21 in the institution on Saturday last. Two cases are reported on the Mumbles lighthouse rock. Up to last Saturday there had been 26 cases of small-pox at Exeter, no less than 20 being traceable to a mild attack in a woman, the disease being for some time unrecognisable as small-pox. Of the 26 cases 6 were of unvaccinated persons, and these furnished the only severe attacks, though not one had then proved fatal. All the 4 cases under seven years of age were in unvaccinated children. The child of a travelling tailor has contracted small-pox at Narberth and has been removed to the workhouse together with the parents.

Parliamentary Intelligence.

CURRENT NOTES.

Irish Pauper Lunatics.

THE Poor Relief Bill for Ireland, which the Government hope shortly to be able to introduce, will deal with workhouse administration and in particular with the detention of the insane poor in workhouses.

Horseless Carriages.

The Government has introduced a Bill to meet the difficulty with regard to horseless carriages, autocars, and vehicles of that description. In the present state of the law these carriages can only be used in the streets under the same conditions as heavy locomotives, which, of course, are out of the question when the speed of ordinary horse traction is required. The Bill provides a heavy penalty for negligent driving and has stringent requirements as to the emission of smoke or visible vapour.

Infant Life Protection.

The Select Committee of the House of Lords, appointed to consider the question of the better protection of infant life and the Bill with that object prepared by the London County Council, began work on Friday, April 24th, when they examined Mr. A. Spencer, chief officer of the Public Control Department of the London County Council, and Mr. Luxmore Drew, coroner for West London. They held another meeting on Monday, April 27th, when they examined Mr. Babey, inspector of the London County Council under the Infant Life Protection Act, and Mr. Braxton Hicks, another of the London coroners.

HOUSE OF COMMONS.

THURSDAY, APRIL 23RD.

Miners' Nystagmus.

Mr. John Wilson (Durham) asked the Secretary of State for the Home Department whether it was part of the duties of an inspector of mines to inquire into the action of the safety lamp as a cause of miners' nystagmus; and whether it would be competent for an inspector to prohibit the use of any class of safety lamps if it were proven that such lamp caused nystagmus.—Sir Matthew White Ridley replied: The answer to both parts of the question is in the negative, but I may add that Mr. Snell of Sheffield, who has written a work on miners' nystagmus, and is still carrying on his investigations into its causes, is afforded such assistance as is in his power by the inspector of the district. The conclusions so far obtained point, I understand, to other causes than the use of safety lamps.

Suicides in the Mercantile Marine.

Mr. Akers Douglas, speaking on behalf of the President of the Board of Trade, stated that the attention of the Board had been drawn to the memorandum by the Registrar-General of Shipping and Seamen with reference to the question of suicides in the engine-room staff of the Mercantile Marine, in which it was said the suicides in the foreign-going vessels are prevalent to a degree calling for serious attention. The President of the Board of Trade had called for further information and would give the matter his careful attention.

FRIDAY, APRIL 24TH.

Cycling Accidents in London.

In reply to another question on this subject, Sir M. W. Ridley said: The return which the police have prepared for me shows that the number of serious accidents caused by cyclists during the first quarter of this year was ten, and the number of slight accidents not requiring treatment, or at any rate detention at a hospital, 174. In no case had the accident a fatal result. No special arrangements have been made by the police, but they use to the full the special powers which they possess under the Metropolitan Police Act, Section 54 of that Act providing that every person who shall ride or drive furiously, or so as to endanger the life or limb of any person, or to the common danger of the passengers in any thoroughfare, shall be liable to a penalty, and may be taken into custody without warrant by any constable who sees the offence committed. So far as serious accidents are concerned the figures I have given may be taken as accurate; it is unlikely that any such accidents have occurred without coming to the notice of the police.

MONDAY, APRIL 27TH.

The Spread of Vermin.

Mr. Hazell asked the President of the Local Government Board whether his attention had been called to the fact that a large and growing number of persons, estimated at from 50,000 to 60,000 in London alone, sleeping in refuges and similar places become infested with vermin, and that the same conditions prevail in some of the larger provincial cities; and whether, since this verminous state hinders even deserving persons in their efforts to get employment and spreads the evil among the general population when they go to the parks and to other places of public resort, he could recommend the sanitary authorities and the Poor-law authorities to permit, as far as they found practicable, all verminous persons who might apply to them, to be cleansed by the aid of the apparatus which these authorities already possess, such cleansing to be without charge and without the applicants being in any way treated as paupers.—Mr. Chaplin replied that as regards the casual wards it was the usual practice to provide for the bathing of the inmates and also the cleansing of their clothes where necessary. With regard to those persons who sleep in refuges, it appeared to him that it would not be unreasonable to expect that those who provide the refuges should also provide the means of freeing the clothes from vermin where required. With regard to the general question as to the sanitary authorities and the Poor-law authorities providing means such as those suggested, for cleansing without charge and in the case of persons who were not paupers, at present it appeared to him that there would be considerable difficulty in carrying out such an arrangement. The subject was, however, receiving his consideration.

Foreign Butter.

Mr. Hanbury, in reply to a question by Mr. Flynn, stated that the Customs officers are still continuing to take samples of foreign butter at some of the ports of entry. In January 118 samples were taken, of which ten were found to be adulterated; in February 179, of which sixteen were found to be adulterated; and in March seventy-seven, of which none were found to be adulterated. So far as the Customs were concerned no steps were being taken to fine or otherwise punish

Digitized by Google

consignees found in possession of adulterated butter, nor had they any legal powers in this particular direction.

TUESDAY, APRIL 28TH.

Coolie Labour in Assam.

Mr. Samuel Smith asked the Secretary of State for India whether he could give the House any information regarding the death-rate of coolies employed in the coal mines of Assam; whether he was aware that the Calcutta Press represented that rate to be very high, and also that a very large percentage were always on the sick list; whether the Indian Government had any information to show that this was caused by a forced change of diet to rice; and, whether the Government could make regulations enforcing the supply to immigrants of the same kind of food they had been previously accustomed to, in the same way as was done for Native soldiers in the Indian Army?—Lord George Hamilton replied that the industry to which the question referred was, comparatively speaking, a very small one, employing little more than a thousand coolies. He had no information as to the death-rate prevailing among them, but he had seen a letter on the subject from a visitor to Assam, published in the Calcutta newspapers, in which it was stated that the death- and sick-rates were high, but no figures were given. The suggestion that evil effects were produced by forced change to rice diet seemed improbable, inasmuch as most of these coolies were drawn from rice-consuming districts. As at present advised he saw no occasion for the issue of regulations on this subject, and he might add that the writer of the letter mentioned bore testimony to the excellence of the existing arrangements for feeding and housing the coolies and for providing them with medical care.

The Horse Leech Question.

Mr. Fell Pease asked the President of the Board of Agriculture if he was aware that a large number of old horses were exported to France, where they were subjected to very cruel treatment by being turned out into marshy land, where they were fastened upon by leeches and thus tortured to death; and if he could prevent the export of old and useless horses likely to become victims of this treatment.—Mr. Walter Long replied that he had seen various statements in the newspapers on this subject, but he had not himself received any representations respecting it. He understood, however, that full inquiries had been made on the spot by the Royal Society for the Prevention of Cruelty to Animals, and that the conclusion arrived at was that the original statement was happily a gross exaggeration. In any case, it would not be competent for him to prohibit the export of horses from this country.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ANDERSON, G. B., M.B., C.M. Edin., has been appointed Parochial Medical Officer by the Cannonbie Parish Council.

BEAUMONT, J. C. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Infirmary and the Gordon-road Workhouse of the parish of Camberwell, vice Chabot, resigned.

BURT, D. J. S., M.B., C.M. Edin., has been appointed House Surgeon to the Brighton, Hove, and Sussex Throat and Ear Hospital, Brighton.

CLARK, R. L., M.B., C.M. Edin., has been appointed Medical Officer for the Maryport Sanitary District of the Cockermouth Union, vice J. Little, resigned.

CRAGO, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Surgeon to the Sydney Hospital, New South Wales.

DALE, FREDERIC, M.D. Cantab., F.R.C.S. Eng., has been appointed Honorary Ophthalmic and Aural Surgeon to the Scarborough Hospital and Dispensary.

DAVIS, S. B., M.B., C.M. Edin., has been appointed Resident Medical Officer and Public Vaccinator for the York District, Western Australia.

FLYNN, R. A., F.R.C.P. Irel., L.R.C.S. Irel., has been appointed Gynæcologist to the Drumcondra Hospital.

FLUX, GEORGE B., M.D. Brux., L.R.C.P., M.R.C.S., L.S.A., has been appointed Anæsthetist to the National Dental Hospital.

FORTESCUE, W. A. J., M.B., C.M. Aberd., has been appointed Medical Officer, Royal Infirmary, Aberdeen.

GARSTANG, T. W. H., M.R.C.S., has been appointed Medical Officer of Health by the Middlewich Urban District Council.

GILL, SAMUEL E., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Resident Medical Officer to the Royal Hospital for Diseases of the Chest, City-road.

GORDON, J. L., M.B., C.M. Aberd., has been appointed Medical Officer, Royal Infirmary, Aberdeen.

GRAHAM, JAS., M.B., C.M. Edin., has been appointed Medical Officer for the Orton Sanitary District of the East Ward Union, vice J. S. Aitken, resigned.

HARVEY, H. F., M.R.C.S. Eng., has been appointed, pro tem., Principal Medical Officer in Western Australia.

HEPBURN, W. A., M.D. St. And., F.F.P.S. Glasg., has been reappointed Medical Officer of Health by the Durham Rural District Council.

JENKINS, GEO. J., M.B., C.M. Edin., has been appointed Resident Medical Officer of the Craiglockhart Poorhouse.

JEPSON, E., M.D. Durh., M.R.C.S., has been reappointed Medical Officer of Health by the Durham Rural District Council.

JONES, HENRY T., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District of the Pembroke Union, vice J. W. Morison, resigned.

JONES, SAM. E., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Shocklack Sanitary District of the Tarvin Union.

LANSDOWN, C. E., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer, York Dispensary.

LITTLEWOOD, J. O., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health by the Skegby Rural District Council.

LOVEGROVE, J. F., M.R.C.S. Eng., has been appointed Government Medical Officer and Vaccinator for the district of Picton, New South Wales.

MUNRO, J. D. R., M.D. Edin., has been appointed Medical Officer of Health to the Nantwich Urban District.

O'MEEHAN, J. A., L.R.C.S. Irel., has been appointed Resident Medical Officer and Public Vaccinator for the districts of Kalgoorlie, East Coolgardie, Western Australia.

PEARSON, R. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Wigan Rural Sanitary District, vice J. A. Marsden, resigned.

PURSER, CECIL, M.B., Ch.M. Syd., has been appointed Honorary Assistant Physician to the Prince Alfred Hospital, Sydney, New South Wales.

REED, H. A., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Public Vaccinator for the district of Ellesmere, New Zealand.

SANDFORD, E. J., M.D. St. And., M.R.C.S., has been reappointed Medical Officer of Health for the Drayton Rural Sanitary District.

SCATTERTY, WM., M.D., C.M. Aberd., has been appointed Medical Officer of Health for the Keighley Urban Sanitary District.

STEWART, C. A., L.R.C.P., L.R.C.S. Edin., has been appointed Acting Officer of Health for Richmond City, Victoria, Australia.

STEWART, G. J. T., M.B., C.M. Aberd., has been appointed Medical Officer, Royal Infirmary, Aberdeen.

SYMONS, WILLIAM HENRY, D.P.H. Oxon. and Durham, and M.I.C., has been appointed Medical Officer of Health by the Bath Urban Sanitary Authority.

THOMSON, A. G. A., M.B., C.M. Aberd., has been appointed Medical Officer, Royal Infirmary, Aberdeen.

TIPPER, ERNEST H., M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond., has been appointed Court Physician to the Independent Order of Foresters, Denmark-hill.

USHER, C. H., M.B., B.C. Camb., F.R.C.S. Edin., has been reappointed Ophthalmic Surgeon, Royal Infirmary, Aberdeen.

WALSHAM, HUGH, M.A., M.B. Cantab., M.R.C.P. Lond., has been appointed Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria Park.

WAYLEN, A. R., M.D. St. And., M.R.C.S. Eng., has been appointed Chairman of the Aborigines Protection Board, Western Australia.

WHICHER, A. H., M.R.C.S., has been reappointed Medical Officer of Health by the Midsomer Norton Urban District Council.

WIGHTMAN, J. P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Rawdon District Council.

WILLIAMSON, W. W., M.B., C.M, Edin., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health for the Lymm Urban Sanitary District, vice Fox, deceased.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BULAWAYO HOSPITAL.—Resident House Surgeon, unmarried. Salary £400 per annum, with free board and lodging. Applications to the Chairman, Hospital Board, Bulawayo, Rhodesia.

BURGH OF LEITH PUBLIC HEALTH HOSPITAL.—Resident Physician for one year. Salary 50 guineas. Applications to the Town Clerk, Town Clerk's Office, Leith.

DENTAL HOSPITAL OF LONDON AND LONDON SCHOOL OF DENTAL SURGERY, Leicester-square, W.C.—Demonstrator. The honorarium is £50 per annum.

GENERAL HOSPITAL, Barbados, West Indies.—Junior Resident Surgeon for three years. Salary £200 per annum, payable monthly, with unfurnished apartments. Applications to the Secretary, Barbados General Hospital.

GLAMORGAN COUNTY ASYLUM, Bridgend.—Junior Assistant Medical Officer. Salary £130, rising £10 a year to £150 if approved, with board (no beer or wine), lodging, and washing.

HOSPITAL FOR WOMEN, Soho-Square, London, W.—House Surgeon for six months. Salary £30 for that period.

KENT COUNTY OPHTHALMIC HOSPITAL, Trinity House, Maidstone.—House Surgeon. Salary, with furnished apartments and attendance in the hospital, but without board, for the first year £125 and £150 after the first year.

METROPOLITAN ASYLUMS BOARD—SOUTH-EASTERN HOSPITAL, Hatfield-street, Old Kent-road, S.E.—Medical Superintendent. Salary at the rate of £400 per annum, rising by annual increments of £25 to £500 per annum, with a partially furnished house, attendance, coals, gas, and washing. Applications to the Clerk to the Board, Norfolk-street, Strand, W.C.

METROPOLITAN HOSPITAL, Kingsland-road, N.E. — Surgeon and Assistant Surgeon.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, Soho-square, London,—Resident Medical Officer for six months. Board, residence, laundry, and an honorarium of 10 guineas for that period.

PLYMOUTH ROYAL EYE INFIRMARY.—Honorary Surgeon.

RANGOON MUNICIPALITY. — Health Officer. Salary Rs. 600 per mensem, rising to Rs.1000 per mensem by annual increments of Rs. 50 per mensem. Applications to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C.

ROYAL SOUTH HANTS INFIRMARY, Southampton. — Assistant House Surgeon for six months. Gratuity of £10 will be given if found satisfactory.

SHEFFIELD ROYAL HOSPITAL.—House Physician, unmarried, for one year. Board (exclusive of wine and beer) and lodging provided, and an honorarium of 25 guineas.

Digitized by Google

STAMFORD, RUTLAND, AND GENERAL INFIRMARY, Stamford.—House Surgeon, unmarried, for two years. Salary £100 per annum, with board, lodging, and washing.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Board and residence provided, and an honorarium of £10 given after six months' satisfactory service.

STRETTON HOUSE PRIVATE ASYLUM.—Resident Medical Officer, unmarried. Applications to Mr. Campbell Hyslop, Stretton House, Church Stretton, Salop.

UNIVERSITY OF ST. ANDREWS.—Lecturers: (1) on Anatomy, salary £300 per annum; (2) on Materia Medica, salary £200 per annum; and (3) on History, salary £200 per annum. The appointments for a term of three years. Application to the Secretary of the University Court, St. Andrews.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W.—Assistant Physician to the Out-patients for five years. Also House Physician to the In-patients for twelve months. Honorarium £50, and board and lodging in the hospital provided.

Births, Marriages, and Deaths.

BIRTHS.

BERRY.—On April 28th, at Wansford House, Watford, the wife of F. Haycraft Berry, M.D. Lond., of a son.

BONTOR.—On April 23rd, at Great Berkhamsted, Herts, the wife of Sidney A. Bontor, M.D., of a son.

CORNER.—On April 26th, at Earlswood Asylum, Redhill, Surrey, the wife of Harry Corner, M.D. Lond., of a son.

HARRISON-GILPIN.—On April 12th, at Bengeworth, Evesham, the wife of R. Harrison-Gilpin, M.R.C.S., L.R.C.P. Lond., L.S.A., M.O.H., of a son.

LONGTON.—On April 24th, at Eaton-road, Hove, the wife of G. Harold Longton, M.R.C.S., L.R.C.P. Eng., of a son.

MARTIN.—On April 23rd, at Arnheim, Blackburn, the wife of John M. H. Martin, M.D. Victoria, F.R.C.S., J.P., of a son.

SANDILAND.—On April 25th, at 137, Southgate-road, N., the wife of A. H. Sandiland, L.R.C.P. Lond., of a son (stillborn).

SAUNDBY.—On April 26th, at Edmund-street, Birmingham, the wife of Robert Saundby, M.D. Edin., of a son.

SOLLY.—On April 24th, at Strathlea, Harrogate, the wife of Ernest Solly, M.B., F.R.C.S., of a daughter.

MARRIAGES.

BÖDEKER—WARDLAW.—On April 28th, at the Parish Church of St. Mary, Stratford-le-Bow, by the Rev. Marmaduke Hare, Vicar, Henry Albert Bödeker, M.B. & C.M., of Moulmein, British Burmah, to Helen, youngest daughter of Sir Henry Wardlaw, Bart, of Pitrearie, Balmule, Tillicoultry, Scotland. No cards.

DAVID—WILLIAMS.—On April 28th, at Llanwonno Parish Church, by the Rev. Llewellyn Lloyd Davies, M.A., W. Washington David, M.R.C.S. Tonypandy, to Anne Williams, daughter of the late Thomas Williams, Y Glog, Llanwonno.

HAIG—WHITTON.—On April 21st, at St. Cuthbert's, Philbeach-gardens, Surgeon-Lieutenant-Colonel Percy de Haga Haig, I.M.S., 1st Punjab Cavalry, to Eleanor Beatrice (Norah), eldest daughter of Brigade-Surgeon G. E. Whitton, of Kensington-mansions, S.W.

LAPTHORN—LEE.—On April 28th, at Union Chapel, Islington, Charles Albert Lapthorn, F.R.C.S.E., of Bletsoe House, Littlehampton, to Agnes Mary, daughter of Henry Lee, J.P., of Earlham, Highbury-quadrant, N.

OVEREND—PAYNE.—On April 22nd, at All Saints', Edmonton, Wilkinson Overend, M.B., B.A. Oxon., of Sheffield, to Elizabeth Russell, eldest daughter of Wm. Francis Willton Payne, of Bringhurst, Bush-hill-park, Enfield.

QUARRY—WARREN.—On April 22nd, at St. Mary's, Winchfield, Hants, Marcus Henry Quarry, M.B., B.Ch. Irel., Medical Superintendent of Lambeth Infirmary, to Ella Mary, eldest daughter of the late L. L. Warren.

STUART—MARKS.—On April 24th, at St. Mary's, Barnes, Alexander Stuart, M.B., C.M. Edin., of Aberdeen, to Agnes Drysdale, daughter of H. Stacy Marks, R.A.

SUTHERLAND—BARWELL.—On April 30th, at St. John's, Hollington, St. Leonard's, by the Rev. W. H. Green, M.A., Vicar, and the Rev. E. N. Powell, M.A., Henry Sutherland, M.D., of Richmond-terrace, Whitehall, to Meta Prescott, second daughter of Captain William Blunt Barwell, formerly 16th Bengal Lancers, and granddaughter of the late General William Prescott.

DEATHS.

ANDERSON.—On April 26th, at Sunnybrae, Pitlochry, N.B., Arthur Anderson, M.D., C.B., retired Inspector-General of H.M. Hospitals, in his 82nd year.

CLARK.—On April 23rd, at Gatestone-road, Norwood, Willington Clark, F.R.C.S., L.S.A., in his 92nd year.

CRAIG.—On April 15th, at Waverley House, Worthing, John Craig, F.R.C.S., late of the East India Company's Service.

HARE.—On April 18th, at Sunnylea, Weymouth, suddenly, Richard William Hare, Surgeon-Lieutenant-Colonel, M.S., aged 57.

HIGHETT.—On April 20th, Charles Highett, M.R.C.P. Edin., of Field House, Montpellier, Bristol.

LOCKHART.—On April 29th, at Granville-park, Blackheath, William Lockhart, F.R.C.S., for twenty-five years Medical Missionary in China (London Missionary Society), aged 84.

MAHONY.—On April 25th, at East Grinstead, Arthur John Mahony, L.S.A., aged 76.

SQUARR.—On April 18th, at 14, Portland-square, Plymouth, William Squarr, F.R.C.S., of pneumonia, aged 51.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.).

TUESDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (6th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Great Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.) Gt. Northern Central (2.30 P.M.).

SATURDAY (9th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (4th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Mr. J. F. Colyer will open a Discussion on The Early Treatment of Crowded Mouths. Mr. G. Brunton: Some Experiments in Colouring Porcelain for Teeth and Gum Body.

SOCIETY OF ARTS.—8 P.M. Mr. J. Swinburne: Applied Electro-Chemistry. (Cantor Lecture.)

TUESDAY (5th).—PATHOLOGICAL SOCIETY OF LONDON.—Papers:—Dr. N. Moore and Dr. Kanthack: Malarial Hæmatozoon in Ashanti Fever.—Mr. J. Smith: Lymph Scrotum with Filaria.—Dr. Arkle and Dr. Hinds (Worthing): Pneumonomycosis.—Mr. Shattock: Healing of Incisions in Vegetable Tissues. Card Specimens: Mr. S. Jones: Bony Tumours of Scalp.—Mr. J. R. Lunn: Aneurysm of Inferior Thyroid Artery.—Dr. H. C. Sharp (Truro): Primary Colloid Carcinoma of Bladder.—Mr. St. C. Thomson: Angeioma of Septum Nasi.—Mr. Targett: (1) Psammoma of Dura Mater; (2) Colloid Duct Cancer and Sarcoma in the same Breast.—Dr. Rolleston: (1) Myeloid Cells in Mammary Sarcoma; (2) Embolism of Coronary Artery; (3) Loose Body Encysted on Convex Surface of Liver.

SOCIETY OF ARTS.—8 P.M. Mr. J. F. Dowling: Australia's Prospects in British Markets.

WEDNESDAY (6th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Lewers, Mr. Doran, Dr. Handfield-Jones and others. Adjourned Discussion on Mr. Morison's, Dr. Spencer's and Dr. Eden's papers on Deciduoma Malignum. Papers:—Mr. A. Doran: Cases of Fibroma of the Ovary and Ovarian Ligament Removed by Operation; with a series of After-Histories of Cases reported in the Transactions since 1879.—Dr. J. Phillips: Anterior Colpotomy.

SOCIETY OF ARTS.—8 P.M. Mr. H. Maxim: High Explosives and Smokeless Powders.

THURSDAY (7th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-st., Cavendish-sq., W.)—8 P.M. Clinical Evening. Mr. A. Critchett: (1) Restoration to Normal Vision after Sympathetic Ophthalmitis; (2) Extraction of a Dislocated Lens with good result.—Dr. R. D. Batten: Optic Nerve Disease in a Mother and Three Children.—Mr. H. Spicer: Case of Spurious Optic Neuritis.—Mr. H. Power: Case of Lightning Stroke of Face without Permanent Lesion of the Eyes.—Dr. D. Mowat: Lymphangiectasis of Eyelids.—Mr. Maclehose: One-sided Sixth Nerve Paralysis, Retraction of Globe and Contraction of Orbicularis on Rotation Inwards.—Mr. B. Taylor: Transplantation of Skin to the Surface of the Eyeball for the Cure of Symblepharon.—Mr. Cartwright: Posterior Lental Opacity, remains of Hyaloid Artery and Coloboma Lentis.—Mr. F. Eve: Case of Detachment of Retina treated by Drainage.

HARVEIAN SOCIETY (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8 30 P.M. Dr. A. T. Schofield: Mental Therapeutics.

FRIDAY (8th).—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. L. Hudson: A Case of Malingering in a Boy aged Eleven.—Mr. E. Ward: Three Cases of Laryngectomy.—Mr. W. A. Lane: A Case Illustrating a condition of Partial Congenital Dislocation of both Hip Joints Forward and Upwards.—Mr. Raymond Johnson; Fracture of the Neck of the Femur in a Young Subject resulting from Dry Caries of the Bone.—Mr. Makins: A Case of Division and Immediate Suture of the Left Vagus.

Digitized by Google

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (4th).—ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

TUESDAY (5th).—ROYAL INSTITUTION.—3 P.M. Mr. C. V. Boys: Ripples in Air and on Water.

WEDNESDAY (6th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

HOSPITAL FOR CONSUMPTION, &c. (Brompton).—4 P.M. Dr. C. T. Williams: The Arrest of Pulmonary Tuberculosis.

THURSDAY (7th).—ROYAL INSTITUTION.—3 P.M. Mr. W. Gowland: The Art of Working Metals in Japan.

FRIDAY (8th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Mr. W. Wingrave: Of Malignant Disease of the Throat and Larynx.

ROYAL INSTITUTION.—9 P.M. Prof. S. P. Thompson: Electric Shadows and Luminescence.

SATURDAY (9th).—ROYAL INSTITUTION.—3 P.M. Mr. F. Corder: Three Emotional Composers—Berlioz.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

AN INSURANCE COMPANY AND A MEDICAL REFEREE.

WE have received from Dr. Sidney A. Bontor of Great Berkhamsted the copy of an interesting correspondence which has taken place between himself and a sickness and accident insurance company. Dr. Bontor was requested by the company to examine a case and the offer was made of a fee of 5*s*. As the examination was a full one he properly pointed out that the fee was insufficient. He then received an offer of 7*s*. 6*d*., and the person insuring having called upon him by appointment was examined to avoid the inconvenience of sending him away. But Dr. Bontor, in forwarding the report, pointed out that the fee was inadequate, and that as he happened to hold a policy with the company he felt compelled to withdraw from it if such fees were tendered to medical examiners. The manager then sent him a fee of 10*s*. 6*d*. and said that he could not see why Dr. Bontor proposed to withdraw his policy, as the fees offered were all the company could afford. Dr. Bontor replied that he was withdrawing because he did not care to support an office which "sweated" his own profession, and pointed out that the medical examiners should be paid for the work they did irrespectively of the amount of the premium. To this the office replied that the company could not afford to pay more and that the fees had to be adjusted to what they could pay and not what they ought to pay. Dr. Bontor now asks us our opinion on the transaction. We think there can be but one opinion on the matter: if the office cannot afford to pay they must "shut up shop." The contention that the office should pay what they can and not what they ought to pay is monstrous.

F. E. S.—We appreciate our correspondent's reasons, but he must not attempt to practise save as an assistant and under the immediate supervision of a qualified man.

Mr. Lawrence Hamilton is thanked for his communication. We have not seen the book in question.

"A FEMALE MEMBER OF THE ARMY MEDICAL STAFF."

To the Editors of THE LANCET.

SIRS,—Referring to the correspondence on this subject which was carried on in THE LANCET for so many weeks in October and November last, may I be allowed to supplement it by further disclosures? Before entering on the general question I beg to state that I have recently discovered Dr. Barry's grave in Kensal Green, and found it in a shamefully dilapidated condition considering the eminence and remarkable history of the deceased. In fact, I feel bound to appeal to the Army Medical Department in particular, and to the medical profession in general, to rescue from oblivion this last memorial of so estimable, however eccentric, a member of its guild—a class of men second to none in nobility of purpose, practical sympathy, and largeness of ideas. The courteous custodian of the cemetery had never even heard of Dr. Barry, much less her antecedents, and only knew the exact locality of her resting place by reference to the annual register of 1865, kept at the gate house, wherein are recorded the following particulars: "Dr. James Barry; number of grave 19,301; square 67; row 6." We proceeded to the spot and found the rough sandstone slab lying on the grass, smashed at its base when it fell or was blown down years ago, utterly ignored and forgotten! The inscription on the tablet is decipherable with some difficulty, as follows:—

DR. JAMES BARRY,
INSPECTOR-GENERAL OF ARMY HOSPITALS.
DIED 15 JULY, 1865. AGED 71 YEARS.

Truly has this distinguished medical officer of the female sex been allowed to die and sleep in "this neglected spot," forgotten by relations, overlooked by friends, undistinguished by the community. It is hard, nay, disgraceful! But it is not too late to mend matters by the erection of a suitable Scotch granite monument, subscribed for by the medical men of the empire, whereon should be recorded in brief the history of Dr. James Barry's unique career and her services to humanity.

To-day I had an interview with the Director-General, A.M.D., and I have seen the official record of Dr. Barry's services, in which she is stated to have been "mentioned in dispatches," "strongly recommended for promotion," "published in General Orders for assiduity and skill during an epidemic in the West Indies," &c. Sir Wm. Macklnnon seemed greatly pleased with the revived interest evinced by the medical profession in Dr. Barry's extraordinary career, and added, "You are aware, I suppose, that Barry was the daughter of a Scotch baronet, Buchan by name, who married one of the Somerset family, and hence the Doctor's great influence at head-quarters through Fitzroy-Somerset, Lord Raglan. She visited his lordship in the Crimea, but was not out there on active service. This may account for her never receiving a distinction. You know she was a strict vegetarian and only drank Cape wine. She served at the Cape during the government of Lord Charles Somerset, and fought a duel with his aide-de-camp. Some years ago I met Sir Josias Cleotè (the aide-de-camp in question) at a public dinner, and he told me the circumstances of the duel in these very words: 'I am the only officer in the British army who has ever fought a duel with a woman. When I was aide-de-camp to Lord Charles Somerset at the Cape a buxom lady called to see him on business of a private nature, and of course they were closeted for some time. Dr. Barry made some disparaging remark about this. "Oh, I say, Cleotè," he sneered, "that's a nice Dutch filly the governor has got hold of." "Retract your vile expression, you infernal little cad," said I, advancing and pulling his long ugly nose. Barry immediately challenged me and we fought with pistols, fortunately without effect.'" It will here be remembered what I stated in my first letter to THE LANCET on this subject, that I met Dr. Barry in 1858, and voyaged in the same cabin with her to Barbadoes, whither she was going on a visit to her old enemy and present friend, General Sir Josias Cleotè, commanding troops in that island. Sir Wm. Macklnnon proceeded to tell me that Dr. Barry was brought up in Malta, and always seemed to prefer tropical or semi-tropical stations; she served in the Mediterranean and West Indies most of her time. "She had a lovely grey Arab in Corfu," he went on, "which, I remember, she gave to one of the Somersets. After all there was no mistaking her build as a woman—broad hips, small feet, for instance—and perhaps you are aware that she left strict injunctions for her corpse to be sewn up in a blanket before being placed in a coffin." Sir William had my novel, "A Modern Sphinx," on his table, and no doubt when he reads it some of the letters from THE LANCET quoted in the Introduction may awaken on his part other and still more interesting reminiscences of this famous female.

I am, Sirs, yours truly,

Savage Club, April 28th, 1896. E. ROGERS, Lieutenant-Colonel.

P.S.—You are aware that my novel, "A Modern Sphinx" (Dr. James Barry or Fitzjames), originally published in 1881 at 31*s*. 6*d*., has been republished in one volume, with seven illustrations, at 7*s*. 6*d*. There are only 100 copies now extant and then the book will be out of print, application for which should be addressed to me, either at the depôt, 20, Buckingham-street, Strand, or here.

MEDICAL CURRICULUM IN NEW YORK.

THE *Maryland Medical Journal* says that Governor Morton of New York has signed the new medical Bill which raises the medical student's course from three to four years, and allows students who enter colleges to graduate under the rules in force when they matriculated. This law applies to all medical colleges in the State.

Surgeon has not enclosed his card.

"GOOD *v.* BAD VACCINATION."

To the Editors of THE LANCET.

SIRS,—"One who Knows" in THE LANCET of April 25th has hurled his anathema at the heads of all who do not holdhis views of certification of vaccination. He insists that four insertions by an operator, which he furthermore requires to be an expert giving up his time to the duty of making a rigid examination of the person vaccinated, is to be the touchstone whereby his fellow practitioners are to be judged. Those who do not come up to his self-constituted standard he prejudges as having a leaning towards anti-vaccination—i.e., as looking askance at vaccination as a prophylactic—and craven-hearted curs who have not the moral courage to oppose the letter of that law the spirit of which he accuses them of breaking.

Fully sensible that criticism when extended to the remarks of "One who Knows" may appear akin to presumption, while opinions diametrically opposed to the conclusions of "One who Knows" must *a fortiori* be prejudged ignorance yet there are arguments, however specious and sophisticated they may appear when coming from the opposite side, which furnish support to and grounds for such opposition. He will allow, for he cannot controvert the same, that the intensity of action of specific febrile diseases, among which we reckon cowpox or vaccination, and the subsequent immunity they confer, does not vary directly as the numerical coefficient which represents the number of seats of primary inoculation. A man is not the less syphilised because he has one primary chancre than he would be if he had had four such. So with the other specific febrile diseases, the number of seats of inoculation bears no tangible proportion to the intensity of the disease. One or two perfect vesicles, I hold, are as much likely to prove a prophylactic against small-pox as four or six such. I anticipate one objection that "One who Knows" may raise as a telling argument in favour of four insertions: it is that statistics drawn from the returns of the small-pox hospitals do not bear me out, as more admissions are made of persons with one or two scars than of individuals showing four such marks; and that the type of disease is milder among four-scarred individuals than those of the two-scar class. But if statistics are worth anything they must be proportionately considered. Now for every one individual in the population of a district who possesses four scars of vaccination there are at least ten who do not possess more than one or two such marks. Make your comparison a proportionate one and you will see that no greater immunity is gained by four seats of inoculation than by two. "One who Knows" considers it a matter of national importance to see all vaccination relegated to properly appointed public vaccinators, who should be debarred from coming into competition with his professional brethren. Is it because he thinks public vaccinators are capable of enticing patients to desert other practitioners and come to them, or is it because the estimate he has formed of the moral capacity of his professional brethren is so low that such work as vaccination is too great to be trusted to them without supervision and inspection by Government officials? Perhaps we may next so far advance our ideas that catheterisation, &c., will come to be considered specialities, and we may read as an advertisement: Public Catheterisers; must give whole time to duty and engage not to practise privately; salary £400. Apply to Town Clerk X.—With apologies for the length of my letter,

I am, Sirs, yours faithfully,

April 27th, 1896. ONE WHO KNOWS NOTHING.

MEDICAL ADVERTISEMENT.

THE following advertisement appears in the *Hobart Town Clipper*:—

[A CARD.]

CHARLES E. BARNARD, M.D.,
Physician and Surgeon,
136, MACQUARIE-STREET, HOBART.

DR. BARNARD having returned from visiting the several hospitals in Sydney and Melbourne, where he has been studying the latest developments of treatment in all branches of Medicine and Surgery, has now resumed general practice.

Specialist in Diseases of the EYE and the EAR.

Dr. Charles Barnard appears on the "Medical Register" as M.D. Aberdeen, L.R.C.P. Lond., M.R.C.S. Eng., and L.S.A. Lond., and his procedure to obtain practice will not commend him to the favourable notice of either his university or the corporations whose diplomas he bears.

CONCENTRATED ANTITOXIN.

THE *Philadelphia Polyclinic* states that Dr. Joseph McFarland of Philadelphia has succeeded in producing a diphtheria antitoxin, of which 10 cc. equal 2000 immunity units. We may add that similarly good results have been obtained in London by Dr. Cartwright Wood, whose methods were described in THE LANCET of April 11th and 18th.

"HEALTH NOTES."

DR. A. C. DUTT sends us a little pamphlet which he has issued for visitors to the seaside, with special reference to Whitby and district. It consists of brief hygienic instructions with the object of enabling the holiday-maker to take his holiday with due regard to physiological laws and without that incessant turmoil whereby the health is injured rather than recuperated. The little pamphlet is clearly written, but Dr. Dutt should remember the obvious objections that may be urged to this kind of literary endeavour.

"SKIN AFFECTION PRODUCED BY WORKING IN TEAK."

To the Editors of THE LANCET.

SIRS,—As the result of personal experience during five years' amateur cabinet making in spare time I can assert—(1) that no sort of skin eruption ever appeared; (2) that any incised wounds if promptly and firmly closed and kept in apposition invariably healed by first intention, i.e., in a few hours; (3) that splinter wounds and deep abrasions incidental to colonial "roughing it" healed as usual without the least suppuration; and (4) at one time I had my nose broken, with severe lacerations of the nasal mucous membrane, from a polo ball, and in consequence of facial ecchymosis and effusion was unable to go out for some days; during the whole of this time I was working in, generally sawing, very dry teak, the fine sawdust found its way into the air passages, &c., but never any discomfort from nasal catarrh or other minor trouble was experienced. For purposes of instruction I very frequently found myself in cabinet makers' workshops; the men would often show me their minor ailments and injuries, even partial losses of digits, &c., and not once did I see any eczema or other skin affection, or ever any suppuration or delay in healing beyond what would be expected in lacerated wounds, and the men never even suggested that when working in teak they were subject to any such disability or annoyance. From results of my own observations, then, I regard the assertions as to the evil effects of teak with absolute incredulity. I may say that the acquired manual dexterity I have since found absolutely invaluable.

I am, Sirs, yours truly,

April 27th, 1896. M.R.C.S., &c.

Sligo.—(1) We refer our correspondent to two excellent lectures by Dr. H. W. G. Mackenzie which appeared in THE LANCET of Sept. 13th and 20th, 1890. Electricity has been useful. The utility of the administration of thyroid extract is not supported by sufficient experience, but benefit is said to have followed it. See Neale's Digest (1837: 5, and the cross references). (2) Our correspondent should send notices to his own patients. Advertisement in a newspaper is decidedly objectionable.

Inquirer should communicate with the Colonial Office. The salaries commence at £200, but as private practice is allowed the best colonies are the best populated.

F.R.C.S. should apply to the Emigration Offices at the Port of Clearance, or to Emigrants' Information Office, 31, Broadway, Westminster.

Dr. James Blair Hartley.—The case is one for not pressing any claim, but graciously accepting accidents and the courteous statement of them.

Mr. W. Downing.—We have no knowledge of the institution in question.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The Arris and Gale Lectures

ON THE

PHYSIOLOGICAL FACTORS INVOLVED IN THE CAUSATION OF DROPSY.

Delivered before the Royal College of Surgeons of England on Feb. 17th, 19th, and 21st, 1896,

BY ERNEST H. STARLING,
M.D. LOND., M.R.C.P.,
JOINT LECTURER ON PHYSIOLOGY AT GUY'S HOSPITAL.

LECTURE I.

THE PRODUCTION OF LYMPH.

MR. PRESIDENT AND GENTLEMEN,—The term dropsy is used to denote the condition in which there is an abnormal accumulation of lymph in the connective tissue spaces, including the serous cavities of the body. Under normal circumstances these spaces contain lymph, but the amount present never exceeds a certain limit. Under no physiological conditions can we speak of the spaces as distended with fluid. Now, the lymph in these spaces is derived from the blood plasma circulating in the capillaries. From these in all states of activity the lymph is transuded, but as fast as it tends to accumulate in the spaces it is removed by an absorbent apparatus represented chiefly by the lymphatics. As I shall show in my second lecture, the lymphatics are aided in this work of absorption, under probably certain defined conditions, by the blood capillaries themselves. In health, therefore, the two processes of lymph-production and absorption are exactly proportional. Dropsy depends on a loss of balance between these two processes—on an excess of lymph-production over lymph-absorption. A scientific investigation of the causation of dropsy will therefore involve, in the first place, an examination of the factors which determine the extent of these two processes and, so far as is possible, of the manner in which these processes are carried out. In the second place, we must inquire how it is that, under the clinical conditions in which we know dropsy to occur, there is an upset of the balance of these two processes in favour of lymph production. My first lecture, then, will deal with the first of the two processes—i.e., Lymph-Production.

In studying the factors which regulate the production of lymph we must have criteria by which we may judge of the amount of lymph produced. To this end several methods are open to us. The most simple method, and one which was the earliest to be used, is the production of œdema. As a rule, as I shall explain later, we may look upon the production of œdema as due to increased lymph-production. Far more delicate, however, than this method is the observation of the lymph-flow from a cannula placed in a lymphatic trunk, which drains the part under investigation. Most delicate of all, but subject, perhaps, to most fallacies, is the ingenious method devised by Roy and used by Lazarus-Barlow, in which the specific gravity of the tissues is determined. The second of these methods is the one by which most work has been done and which I have used almost exclusively in my own investigations. It is evident that the only constant source of a lymph-flow must be the bloodvessels, and our first object must be to see how the amount and composition of the lymph formed in any given part may be changed by experimental alterations of the pressure and chemical composition of the blood flowing through the capillaries of that part as well as by changes in the walls of the capillaries themselves. In dealing with the functions of any part of the body we can often obtain hints as to the manner of its working from a study of its structure, and I would like, therefore, in the first place to draw your attention to some points in the structure of blood capillaries. These have long been known to consist of tubes whose walls are formed of a simple layer of flattened, nucleated endothelial cells, which are united together by a small amount of cement substance, as it is called, the lines of junction between the cells staining deeply with nitrate of silver. A Russian observer, Kolossow, has added somewhat to this simple account. According to this observer each endothelial cell consists of two parts, a hyaline "ground-plate," which immediately borders the lumen of the capillary, and outside this a protoplasmic granular part in which is embedded the nucleus. The ground-plates of the adjoining cells come in intimate contact with one another, but are in no way continuous, so that there is a linear cleft between the adjacent portions of every two cells. The protoplasmic portions of the cells, on the other hand, are continuous with one another by means of processes. If the capillary be stretched in any way the ground-plates, which are inelastic, are separated from one another, so that the clefts between them are increased in size. Hence we see in nitrate of silver specimens made under these conditions that the lines of reduced silver are much broader than in normal capillaries. Outside the capillary one finds in most instances an ill-developed adventitia which is continuous with the surrounding connective tissues. The picture thus afforded of a capillary must suggest at once that it will not be, so to speak, water-tight, but will permit of filtration between the cells, and if this were the case we would have to look upon the lymph, which is separating from the plasma circulating through the capillaries, as a filtrate. The fact that the lymph from most parts of the body contains less proteid than the blood plasma is no argument against this hypothesis. If we filter serum through porous filter paper the filtrate will have the same composition as the original serum. If, however, we take a more closely-meshed filter, such as a porous clay cell or an animal membrane, we shall find that the filtrate is considerably poorer in proteid than the original serum, the big proteid molecule being apparently unable to go through the smaller pores of such a filter. Now this hypothesis, that the lymph is to be looked upon as a filtrate under pressure from the plasma, has been the guiding idea in the most important works on lymph-formation which have appeared during this century. Though we find it more or less distinctly in the works of the older writers—Hales, Hewson, and others—it is to Ludwig and his pupils that we owe its most systematic examination. According to this hypothesis, the amount of lymph produced in any given part must be proportional to the difference between the pressure in the capillaries and the pressure in the extra-vascular spaces In most of Ludwig's earlier experiments on the subject this condition was found to hold good. On leading defibrinated blood through a limb the lymph-production in the limb was found proportional to the pressure at which the blood was led through it. In the testis ligature of the pampiniform plexus was found to increase largely the lymph production in this organ. In the arm and in the leg extensive ligature of the veins led to an increased flow of lymph. In all these cases, therefore, an increased flow of lymph was obtained by increasing the capillary pressure of the part. Ludwig found it more difficult to prove any constant alteration of lymph production incident on vaso-motor changes, although Rogowicz, working later in Heidenhain's laboratory, found that vaso-dilatation did give a certain definite increase in lymph-production, and also showed clearly that the vaso dilatation of the tongue produced by excitation of the lingual nerve was followed by an increased lymph-production in the tongue, which might at times amount to an actual unilateral œdema of this organ.

In dealing with the laws affecting lymph-production one is hampered by the fact that in the limbs of an animal at rest there is under normal conditions no lymph flow at all, so that when we wish to study the effects of our various procedures on the lymph-production in the limb we have artificially to bring about a lymph-flow by kneading and massaging the limb. Now this fact introduces at once an arbitrary element into the experiment, and Heidenhain suggested, therefore, that the best place to investigate the truth of the filtration hypothesis would be on the lymph-flow from the thoracic duct. This writer, therefore, carried out a long series of researches on the various conditions in which the lymph-flow from the thoracic duct might be increased or diminished, and came to the conclusion that the results of his experiments were irreconcilable with the filtration doctrine, and that we must assume that the cells forming the walls of the capillaries take an active part in lymph-formation—i.e., that lymph must be looked upon as a secretion rather than as a transudation. A renewed examination of Heidenhain's experiments, combined, however, with a more thorough investigation of their conditions, has shown me that, so far from overthrowing the filtration hypothesis, they furnish the strongest arguments which have yet been adduced in its favour.

Digitized by Google

In dealing with the lymph-flow from the thoracic duct it is essential to know from what parts of the body this lymph is derived, especially since, as is well known, the lymphatics from all parts of the body, with the exception of the right upper extremity and right side of the neck, converge to pour their contents into this duct. In placing a cannula in the duct in order to collect and measure the lymph the ducts from the left side of the neck and left upper extremity are ligatured. From the hind limbs we know that in an animal at rest on the table there is no lymph-flow at all. Hence the sources of the lymph are confined to the trunk. We can, moreover, exclude the thorax and its contents, since ligature of the thoracic duct just above the diaphragm absolutely stops the lymph flow. Therefore, when dealing with the lymph-flow from the thoracic duct we deal only with the lymph coming from the abdominal viscera. As I shall show presently, the abdominal viscera, so far as their lymph is concerned, may be divided into two groups: (1) the viscera drained by the portal vein, and (2) the liver.

In testing the filtration hypothesis on the lymph-flow we have to investigate whether the flow is always proportional to the difference between the intra- and extra-capillary pressures. We may regard the extra-capillary pressure as not varying to any large extent, so that we have to see what effect is produced on the lymph by variations in the intra-capillary pressure in the intestines and the liver. The simplest experiments on the subject are those in which some large vessel is obstructed. Speaking generally, we may say that obstruction of a large vein raises the pressure in the capillaries immediately behind it, whereas obstruction of an artery will diminish the pressure immediately in front of it. If, for instance, we ligature the portal vein the arterial pressure is very little affected, while the pressure in the vein behind the ligature rises enormously. In consequence of this there is a large rise of pressure in the capillaries of the intestines and spleen, so that the spleen swells and the intestines become black from venous congestion and hæmorrhages are produced into their mucous membrane. The effect of this ligature on the lymph-flow from the thoracic duct is to increase it four or five times. The lymph also becomes bloody and its total solids are diminished. The diminution in solids is due solely to a diminution in proteids, the salts remaining the same as before, so that we have here an increased capillary pressure, causing an increased transudation of lymph containing a diminished percentage of proteid—a result which is also obtained when proteids are filtered with pressure through dead animal membranes. The presence of red blood-corpuscles in the lymph is not a necessary consequence of a rise of pressure in the portal vein. If a less excessive rise of pressure be produced by ligaturing the vein, not at its entry into the liver, but just below the pancreatic duodenal vein, thus leaving a circuitous route for the blood to the liver through the anastomoses of this branch, an increased flow of lymph is produced, containing less proteids than normal lymph, but which may be quite free from blood corpuscles.

A still more striking effect is produced by obstructing the vena cava just above the diaphragm. The lymph is increased from ten to twenty-fold, and it is found that the lymph obtained after the obstruction is free from red blood corpuscles and is more concentrated than normal lymph. What is the cause of this increased lymph-flow and why is it more concentrated? To answer these questions we must find out, firstly, the source of the lymph, and, secondly, the condition of the capillary pressure in the organ or organs from which the lymph is derived. We can determine the source of the lymph by a process of exclusion. Ligation of the kidney vessels and lymphatics has no effect on the usual consequences of obstructing the inferior vena cava. On the other hand, if we ligature the lymphatics in the portal fissure which carry off the liver lymph we find that a subsequent obstruction has no effect on the lymph-flow, or, indeed, may slightly diminish it. We must conclude then that the increased flow of lymph is more concentrated than intestinal lymph. In order to answer the second question as to this increased production of lymph in the liver we must investigate the changes in the circulation produced by the obstruction. On obstructing the inferior vena cava and recording the blood pressure in the chief vessels of the abdomen we notice that the pressure in the aorta drops almost at once to a third of its previous height, whereas there is a very considerable rise of pressure both in the portal vein and inferior cava. It is probable that the effect of the rise of portal pressure on the intestinal capillaries is more than counterbalanced by the severe fall in arterial pressure, so that there is a fall of pressure in the intestinal capillaries. This conclusion is borne out by the fact that if the abdomen be open the obstruction of the inferior vena cava is seen to be at once followed by a blanching of the intestines; on the other hand, the effect of the simultaneous rise of pressures in the portal vein and vena cava must be to raise the pressure in the capillaries of the liver to three or four times the normal amount. We have, then, as the results of this experiment, no rise of pressure in the portal area and no increase of lymph-flow from the portal area, a large rise of pressure in the hepatic capillaries, and a very large increase of lymph-flow from the liver.

The only other experiment of this nature which I need describe is one in which the thoracic aorta is obstructed. The results of this obstruction on the lymph-flow are somewhat variable. In most cases the lymph is diminished to one-half or one-third its previous amount; in a few cases the lymph is unaltered in quantity or even slightly increased. In all experiments the amount of proteids in the lymph is increased. Now if we investigate the state of the circulation under these conditions we find that obstruction of the thoracic aorta causes an enormous fall of pressure in the aorta below the obstruction and a corresponding fall in the portal vein, whereas the pressure in the inferior vena cava is unaltered or in some cases even slightly increased. We must conclude, therefore, that in the intestinal capillaries the pressure has fallen considerably below its normal limits, while in the hepatic capillaries the pressure is very little altered or may even be somewhat increased. Hence the only region of the body below the point of obstruction where the capillary pressure is not much diminished is the liver. Now we find that the liver is also the sole source of the lymph obtained under these circumstances. If the hepatic lymphatics be ligatured and the thoracic aorta be then obstructed, the flow of lymph from the thoracic duct is absolutely stopped. In these three cases, therefore, the lymph production in the organs of the abdomen is found to be absolutely proportional to the changes of the capillary pressures in these organs. In another set of experiments we find that a marked increase in the lymph-flow is produced by a general rise of capillary pressure in all the organs of the abdomen. Such a general rise of capillary pressure may be produced by the injection of large quantities of normal saline fluid into the circulation, giving rise to a condition of hydræmic plethora. Under such circumstances the lymph may be increased from 50 to 100 times in amount, and may in some cases run from the cannula in the duct in a steady stream. Now, in hydræmic plethora there are two changes in the circulation which might possibly be responsible for the increased production of lymph: firstly, the change in the composition of the blood, and, secondly, the increased pressure in the capillaries of the abdominal viscera. We can decide which of these two factors is responsible for the increased lymph-flow by a very simple experiment. Previously to injecting 300 c.c. of normal saline we bleed the dog to 300 c.c., so that after the injection the total amount of circulating fluid is the same as at the beginning of the experiment. In this way we entirely avoid any rise of capillary pressure, while we have diluted the blood to an even greater extent than in the experiments in which hydræmic plethora was produced. The effect of such a simple hydræmia is to increase the lymph-flow from 3 c.c. in 10 minutes to 4 or 6 c.c. in 10 minutes, whereas if hydræmic plethora were produced the lymph would be increased from 3 c.c. to 30, 50, or 100 c.c. in 10 minutes. It is evident, therefore, that in the production of this increased lymph-flow the all important factor is the rise of capillary pressure.

Exactly the same interpretation holds good for the action of a certain class of bodies which were grouped together by Heidenhain in the second class of lymphagogues. These include bodies such as salt, sugar, potassium, iodide, &c. The injection of a strong solution of dextrose (30 grms. in 30 c.c. water) into the veins of an animal causes a considerable increase in the lymph-flow from the thoracic duct. The lymph at the same time becomes more watery than at the commencement of the experiment. Heidenhain ascribes this effect to a specific excitation of the secretory activities of the endothelial cells. The effect, however, can be explained in a much more simple fashion. All these solutions have an osmotic pressure which is considerably higher than that of normal blood plasma. A solution of dextrose that should be isotonic with the blood plasma would contain from 5 to 6 per cent. of this body. When we inject a solution containing

Digitized by Google

from 50 to 75 per cent. of dextrose it will attract fluid from the tissues until its percentage is reduced to 5 or 6 per cent., that is to say, 45 c.c. of fluid containing 30 grms. of dextrose will attract water from the tissues until its total volume is increased to 500 c.c. Of course, this estimate is merely a rough approximation at the truth, since before the sugar has had time to attract all this fluid a considerable amount of it will already have left the vessels by diffusion. As a matter of fact, however, we find that injection of a strong solution of dextrose is followed in a few minutes by a considerable dilution of the blood, caused by an increase in its volume. In some experiments of von Brasol the volume of the circulating blood was thus increased to twice or three times its previous amount; and these observations have been fully confirmed in a series of careful experiments made by J. B. Leathes. As we should expect, this increase in the volume of the circulating blood is attended by a large rise of capillary pressures in the abdominal viscera, and we have here again to decide whether it is this rise of capillary pressure or the change in the chemical composition of the blood that determines the increased lymph-flow. This question can be solved by using the same method that we adopted when dealing with the production of the increased lymph-flow in hydræmic plethora. We can entirely obviate the rise of capillary pressure if we bleed first to 300 c.c. and then inject a concentrated solution containing 18 grms. of dextrose. In this case the fluid that is dragged by the sugar from the tissues into the blood-vessels only just suffices to make up for the previous loss of blood. No hydræmic plethora is produced; there is no rise of capillary pressure, and there is no increase in lymph-flow, although an abnormally large amount of dextrose is present in the circulation. We must conclude, therefore, that the increased flow of lymph caused by injection of the second class of lymphagogues is entirely due to the rise of capillary pressure thereby induced, and is in no wise conditioned by a stimulation of the secretory activities of the endothelial cells.

There is one point in the effects of the injection of these bodies which has been looked upon as a strong argument for the secretory hypothesis, and which I must therefore mention shortly here. If we analyse the lymph and the blood at different periods after the injection we find that the amount of sugar in the blood steadily diminishes, while the sugar in the lymph first rises to a maximum and then diminishes parallel with that in the blood plasma. At a given period after the injection it is found that the lymph contains more sugar than does the blood plasma, and this fact was held to point to an undoubted secretory activity of the endothelial cells in the production of lymph. This conclusion, however, is by no means justified. The lymph flowing at any given moment from the thoracic duct does not represent the transudation from the blood at that moment, but is derived from the lymph that has been formed some time previously. If we had a solution of sugar in gradually diminishing strength flowing into a lymphatic trunk of the leg it is evident that this fluid would mix with the lymph in the other lymphatics, through which it flowed on its way to the thoracic duct. Later, the solution of sugar would have displaced practically all the lymph from these channels and would flow through the thoracic duct almost undiluted. It would take, however, some considerable time to flow from the leg to the thoracic duct, so that the outflow from the duct would represent not the fluid which was being injected into the leg at that moment, but the stronger solution which had been flowing in some time previously. If one compared, therefore, the percentage of sugar in the fluid flowing from the duct and in the fluid flowing into the leg lymphatic at different times after the beginning of the injection we should obtain a curve exactly similar to those obtained by Heidenhain after the injection of sugar into the circulation, and looked upon by him as undeniable evidence of secretory activity.

The dependence of lymph-formation on capillary pressure is not, however, the only important relationship brought to light by these experiments. The amount and composition of the transudation through a membrane depend not only on the pressure at which the transudation is effected but also on the nature of the membrane. According to the permeability of the membrane, so the amount and composition in proteids of the transuding fluid will vary. You will doubtless already have noticed that after obstruction of the inferior vena cava the pressure in the intestinal capillaries, although it probably sinks below its normal height, is yet as high as that in the hepatic capillaries. Nevertheless, we get a very small amount of transudation through the intestinal capillaries and a very large amount through the hepatic capillaries. It is evident, then, that the permeability of the liver capillaries must be very much more marked than that of the intestinal capillaries. In the same way we may compare the permeability of the intestinal capillaries with those of the limb capillaries. Normally from the limb there is no flow of lymph at all, whereas a probably equal pressure in the intestinal capillaries suffices to give rise to a steady flow of lymph. If we ligature all the veins of the leg a lymph-flow may be set up, but such a flow is incomparably smaller than that produced on ligature of the portal vein. We can, therefore, arrange the capillaries of the body in a descending order of permeability, the liver capillaries being the most permeable and the limb capillaries the least permeable. I have already mentioned how, on filtering solutions of proteids through various membranes, the percentage of proteids in the filtrate increases with the permeability of the membrane. As we have seen, exactly the same thing holds good for the capillaries in the body. The lymph in the limbs, the filtrate through the impermeable limb capillaries contains only from 2 to 3 per cent. proteids. That from the intestines contains from 4 to 6 per cent. proteids, while that from the permeable capillaries of the liver contains from 6 to 8 per cent. proteids—in fact, almost as much as the blood-plasma itself. It is conceivable that we might alter the amount of lymph produced in any organ by changing, not the intracapillary pressure, but the filtering membrane—i.e., the endothelial wall of the capillaries. Such a change can be brought about in the body by various means. A whole group of bodies has been described by Heidenhain as his first class of lymphagogues. These substances, which are mostly of the nature of albumoses, can be extracted from various of the lower animals and include leech extract, mussel extract, crayfish extract, and commercial peptone. On injecting a small amount of any of these extracts into the bloodvessels of an animal the lymph from the thoracic duct is much increased in quantity and becomes more concentrated. Now all these bodies are poisons; they alter the blood, diminishing its coagulability, and when given in sufficiently large doses cause a great fall of blood pressure in consequence of paralysis of the heart and vessels. I have shown that the changes in the circulation produced by these bodies are insufficient to account for the increased lymph-flow, but that the increased flow is due to an alteration of the capillary walls in the abdominal organs, especially in the liver. The hepatic capillaries become even more permeable than before, so that a pressure within them which is little above normal is sufficient to cause a great increase of transudation through them.

Another substance which seems to act directly on the capillary wall is curare. This body, however, differs from the class of lymphagogues just mentioned in the fact that its chief action is on the vessels of the limbs. The effect of curare in increasing the lymph-production in the limbs was noticed long ago by Paschutin working in Ludwig's laboratory. Its direct action on the endothelial wall of the capillaries can be easily demonstrated in the living frog's web. It may be seen that after the injection of curare the capillary walls become apparently more sticky, so that the capillaries become filled with a number of leucocytes adhering to their walls. A still more potent method of altering the permeability of the limb capillaries is to plunge the limb into water at 56° C. for some minutes. If a cannula has been previously placed in one of the main lymphatics of the leg it will be noticed that, in a very short time after this scalding, lymph begins to drop spontaneously from the cannula. The lymph which is thus produced is much richer in proteids than is lymph from a normal leg. The amount of lymph flowing from the leg can now be varied within wide limits by altering the pressure in the capillaries either by ligature of the vein or artery, injection of salt solution, or production of vaso-motor paralysis. By this scalding, in fact, we may reduce the limb capillaries to the condition of liver capillaries.

In conclusion, from this study of the conditions of lymph-production in the various parts of the body we must conclude that the endothelial cells of the vessels take no active part in the production, their vital activities being confined to the maintenance of their integrity as a filtering membrane with properties differing according to the part of the body in which they happen to be situated. The amount and composition of the lymph transuded in any part are determined solely by two factors: (1) the permeability of the vessel wall

Digitized by Google

and (2) the intracapillary blood pressure. The more permeable the capillary the greater is the amount of lymph transuded under any given pressure, the greater is its concentration in proteids, and the more easily is the amount of lymph altered by slight changes of pressure.

The Hunterian Oration:

REFLECTIONS ON JOHN HUNTER AS A PHYSICIAN AND ON HIS RELATION TO THE MEDICAL SOCIETIES OF THE LAST CENTURY.

Delivered before the Hunterian Society on Feb. 13th, 1896,

BY G. NEWTON PITT, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR ASSISTANT PHYSICIAN, LECTURER ON PATHOLOGY, AND DEMONSTRATOR OF MORBID ANATOMY AT GUY'S HOSPITAL, ETC.

[THE first part of the Oration dealt with the life of Hunter and his experience as a physician, which was shown to have been by no means inconsiderable. Dr. Newton Pitt then continued as follows:]

Until the latter quarter of last century, as Mr. Quain pointed out, there was no medical education in London. Surgeons and apothecaries were supposed to be able to pick up a sufficient smattering of their work by attending the hospital for a few months, and physicians were educated elsewhere. Some half-dozen each year took the degree of M.D. at the Universities of Oxford or Cambridge, and these alone could become Fellows of the College of Physicians of London, while a much greater number proceeded to medical degrees either abroad or at Edinburgh. Owing to the genius and energy of the elder Monro and others, the education at Edinburgh was far ahead of anything in London, and we naturally find that medical societies and periodicals flourished there before they became established in the south.

Before knowledge can be classified and accurate conclusions drawn, it is necessary that a large amount of material should be collected from many sources. The formation of medical societies and the publication of transactions and periodicals form a feature in the medical history of the last century, contrasting strongly with that of the seventeenth century. Previously to this the Memoirs of the Royal Academy of Sciences in Paris and the Philosophical Transactions of the Royal Society of London were almost the only publications in which English medical cases were reported. Many English physicians had graduated at Paris, and the Philosophical Transactions contain, up to the end of the century, over 1000 medical papers. A large number of medical men have received the honour of the Fellowship of the Society, and not the least distinguished of these was John Hunter, who contributed numerous papers, for the most part dealing with questions of natural history.

Edinburgh Medical Societies.—The School of Physics was initiated in 1720 on the lines of the University of Leyden, and in 1783 there were 400 students of medicine. The *Medical Society* was founded in 1731, the records reach back as far as 1737 and the members received a charter in 1778. This society collected and published five volumes of medical essays and observations between the years 1733 and 1744. Cullen, Hunter, Oliver Goldsmith, Fothergill and Richard and William Budd were among the members. The Society met every Saturday evening during the winter sessions when papers were read. The publications were largely contributed by the first Monro—i.e., John—whose marvellous energy and ability contributed so essentially to the success of the school. He contributed papers on the nutrition of fœtuses, on the diseases of arteries, on the lacrymal canal, on white swelling, on herniæ, on the obstruction of ureters by stones, on ulcers, on procidentia uteri, on the preparation of bodies for dissection, on the anatomy of the lower jaw and of the duodenum, on chalybeate waters, and on new instruments, a range of original work unequalled at that time in this country. *Medical and Philosophical Commentaries* by a society of physicians in Edinburgh were edited by Dr. Andrew Duncan and 20 volumes were issued between 1773 and 1799. They were continued as the Annals of Medicine till 1804. The publication consisted of reviews of books, original medical observations, and medical news. They form the most valuable contemporary record of medical activity of London quite as much as of Edinburgh. The *Philosophical Society* published three volumes under the title "Essays and Observations, Physical and Literary," between 1754 and 1771. The *Æsculapian Society* was instituted in 1774, and consisted of five physicians and ten surgeons, who met and supped together once a month. The *Edinburgh Harveian Society* was founded in 1752 and the *Abernethian Society* in 1785. The *Royal Physical Society of Edinburgh* was founded in 1771, incorporated in 1788, and merged with the Chirurgico-Medical Society in 1796. The *Royal Society of Edinburgh* dates from 1783; the *Hibernian Medical Society*, Edinburgh, from 1791.

The only medical society in *England* outside London was the Medical Society of Colchester, instituted in 1774.

An examination of the history of the societies which were started in London shows that each society owed its origin to the energy of one or two men, and in many instances the society faded away at their death. Until the latter part of the century there was no education for students in London beyond that given by a few private lecturers. As late even as 1783 we learn from the Medical Register that the following was the complete list of lecturers in London. Anatomy: Mr. W. Cruickshank, at the Hunterian Museum in Great Windmill-street; Dr. R. Maclaurin, at his house in Mark-lane; Mr. Blizard, at the London Hospital; Mr. John Sheldon, at his house in Great Queen-street; and Mr. Henry Cline, at St. Thomas's Hospital, who had also been appointed Professor of Anatomy to the Corporation of Surgeons in 1781. Surgery: Mr. Percival Pott, F.R.S., at St. Bartholomew's Hospital; Mr. John Hunter, F.R.S., in the Haymarket; and Mr. J. O. Justamond, F.R.S., in Macclesfield-street, Soho. Physic: Dr. Fordyce, at his house in Essex-street and at St. Thomas's Hospital; Dr. Saunders, at Guy's Hospital; and Dr. Maddocks, at the London Hospital. Most of the lectures, it will be seen, were not delivered at the hospitals, but at the lecturers' houses, where several of them had large schools; and from Mr. Rivington we learn that the school of the London Hospital first offered a complete course of education in 1785 and commenced to give clinical lectures in 1792. From the minutes of the Corporation of Surgeons we learn that their Professor of Anatomy gave a yearly course of six lectures on the muscles and of six on the viscera, the proposal that he should also give three on the bones having been rescinded.

The following appear to be the chief of those to whom the new medical societies were due:—William and John Hunter, John Sheldon, Dr. Foart Simmons, Dr. Saunders, Dr. Fothergill, and Dr. Lettsom. The societies may be divided into two classes, those started by practitioners for the purpose of publishing cases and those started by teachers as a means of keeping in touch with students and junior practitioners and of teaching them how to report and discuss cases. In most instances the possession of a library, from which the members could borrow books, was considered a very essential and important feature. In the student societies, at any rate, the money was raised by innumerable fines rather than by fixed subscriptions.

The Fellows of the Royal College of Physicians used to meet from time to time to discuss medical questions and they issued six volumes of Medical Transactions between the years 1772 and 1820.

The societies associated with William Hunter were the two medical societies of 1753 and 1764. They were both small; the former consisted of physicians and the latter of licentiates. The first society published at intervals the volumes of medical observations and inquiries, and nothing more was heard of the societies after Dr. Hunter's death.

The Medical Society (1).—The first medical society in London was founded in 1752 by some hospital physicians who met together for their mutual improvement in the practice of their profession once a fortnight on Monday evenings at the Mitre Tavern, Fleet-street. After some time they decided to form themselves into a society for collecting and publishing "Medical Observations and Inquiries," six volumes of which were issued between the years 1757 and 1784, the first paper

Digitized by Google

being dated 1753. The preface to the first volume states that "it is much to be regretted that the medical essays and observations of the Medical Society of Edinburgh have been discontinued, and that the present may be in some degree considered as a continuation of that valuable work." The chief contributors were Dr. J. Fothergill (whose museum Dr. W. Hunter bought), Dr. W. Hunter, Dr. G. Macaulay, Dr. S. Pye, Dr. C. Clephane (who died in 1762), Dr. W. Fordyce, and Dr. Gowin Knight. Dr. Hunter was the chief contributor; he was an original member and became the most influential. The society, which then consisted of seven physicians (six of whom were Fellows of the Royal Society), ceased to exist in 1784, after Hunter's death. Among the more interesting contributions I may refer to a case of Hernia of the Abdominal Viscera into the Thorax, reported by Dr. Macaulay; an excellent case of Pharyngeal Pouch, by Mr. Ludlow; a typical case of Osteo-malacia; and to papers by Dr. Fothergill on the Influenza Epidemics of 1758, 1775; on the Objections to Venesections in Apoplexy; and on the Value of Ipecacuanha in Dysentery. Fothergill also gives one of the first accounts of Sick Headache with Visual Disturbances and Fortification Figures, evidently drawn from personal experience; we know from his "Life" that he was constantly incapacitated by its attacks. Dr. Hick, in 1768, reported a case of Strangulation of Intestine under a band, about which he consulted John Hunter, who explained that it had probably arisen from adhesion of the omentum to both the mesentery and the ileum, and was able to show him two similar specimens of bands. In the same volume a case of Cæsarean section is reported, which was performed by Mr. Thompson of the London Hospital, assisted by Mr. Hunter; five years later William Cooper asked Hunter to perform the operation for him and remarks that the whole was conducted with the utmost coolness, humanity, and skill. There is no lack of evidence among contemporary records, of the high value which was set upon Hunter's practical surgical skill by practitioners. In one case he removed a tumour from the side of the neck as large as a head, and by bringing the edges of the skin together the whole nearly healed by primary union, no slight feat in those days.

Dr. Routh, in his Oration in 1859 before the London Medical Society, dealing with its history, states that there is a copy of the laws of this 1753 society in the British Museum which gives John Sheldon as the President for the years 1779 to 1782. On examination I find that this is an error, and that the laws referred to are those of the Great Queen-street Society, to which I shall allude later on. As the 1753 society consisted only of seven somewhat senior physicians it is improbable that there would be anything but the briefest manuscript note of their proceedings.

The Medical Society (2).—Another society of physicians with which Dr. William Hunter was connected, was instituted about 1764, and met once a fortnight on Wednesday evenings at Old Slaughter's Coffee House for the purpose of discoursing on the prevailing diseases. The members were Licentiates of the Royal College of Physicians of London. In 1783 there were twenty-three members, including Garthsore and Robert Bromfield, Hunter's colleagues at the British Lying-in Hospital, George Fordyce of St. Thomas's Hospital, and William Saunders of Guy's Hospital, after which date I have not been able to trace the society. The society was originated by Dr. Alexander Russell, formerly of Aleppo. The members also dined together once a quarter at the Crown and Anchor Tavern in the Strand. The immediate object which those who started the society had in view was to oppose the proposal that Licentiates should be admitted upon an examination in English, which, it was thought, would lower the standard.

The Physical Society.—This society appears to have been instituted at Guy's Hospital in 1771, according to the stamp which is impressed on the books belonging to their library, most probably by Dr. Saunders, who gave the first course of lectures at the hospital in 1770. The book of the laws of the society is dated 1775. The early minute books of the society have for many years been lost sight of, but I have been fortunate enough to discover the volumes from 1783 to 1820, with the exception of those for the years 1786 to 1788 and 1798 to 1804. As was the case with other societies, it would appear that when they were first initiated the members met informally and did not keep minutes of their proceedings. The first existing entry is for Oct. 4th, 1783, with Mr. Cline in the chair, which is headed the first meeting of the second session; while in 1792 we find the secretary making a note that the sessions should have been counted from 1775, and in future this was done. It is probable, therefore, that the meetings became much more businesslike and formal in 1783, but had been taking place for some years. The meetings appear to have been held every Saturday evening from October to May in the theatre of Guy's Hospital, and the society consisted of ordinary, honorary, and corresponding members. The former were required to attend every evening on pain of being fined, and in turn to read a dissertation before the society. After having read two dissertations and attended regularly for two sessions they could be elected honorary members and were freed then from responsibilities. Those physicians, surgeons, and apothecaries who had already distinguished themselves were at once eligible for election as honorary members. The society possessed a library which was supported by a contribution of sixpence from each member at every meeting and of a shilling if he were absent without good excuse. The rules, it is seen, are much more stringent than those that any society enforces at the present time. In the earlier minute-books the most important contributors were Mr. Cline, Mr. Hewson, and Mr. Astley Cooper, who had all been pupils of Hunter; Dr. Babbington, Dr. Saunders, Dr. Lowder, and Dr. Skeete, who were all ultimately on the staff of Guy's Hospital; while Dr. Wells, Dr. Lister, and others of the staff of St. Thomas's Hospital also joined the society. The society also included most of the general practitioners in the neighbourhood and a few from distant parts of the country. Dr. Lettsom, who was a member, was a donor of books to the library.

It is not surprising that there should be frequent reference in the minute books to Hunter's methods of treatment and to his views on many questions, seeing that so many members had been his pupils. Thus, on December 24th, 1785, we read that Dr. Saunders reported an experiment which Mr. J. Hunter had performed for the cure of the popliteal aneurysm. "An incision was begun a little below the middle of the thigh and continued three inches downwards in the course of the artery, and four ligatures were made on the artery above its dilatation with the view to obliterate the aneurysm." This refers to Hunter's first and celebrated operation in this region. Several cases were reported during the next few years successfully treated by the method thus laid down by Hunter. The high estimation in which Hunter was held in this society is shown by the fact that the name of no other surgeon is quoted constantly, while his opinion is several times given as authoritative.

At each meeting the medical cases of interest were first described and then a dissertation was read and discussed. In 1783 the treasurer of Guy's Hospital, Mr. Harrison, was elected a member of the society, and when he was visiting his sister Mrs. Cripps at Cirencester he made the acquaintance of Dr. Jenner, who read one of his earliest papers on Vaccination, at his invitation, before this society. I have not found the entry of this in the minute book, but those for the period 1798 to 1804 are unfortunately missing. Three prize dissertations on the subject have, however, been preserved, one by Dr. John Power of Market Bosworth in the year 1799, but neither the writer nor the date of the others can be traced, but we know that Mr. Allen, the founder of the firm of Allen and Hanburys, attended a meeting in 1802 with Mr. A. Cooper to hear such a paper. Of the numerous cases recorded in the minutes there is but little that is of interest now; on various evenings many different opinions were brought forward as to the value of styptics, such as Ruspini's and agaric, and numbers of cases are reported which had been treated by digitalis and by bark, which latter was largely introduced into this country by Dr. Saunders, Dr. Relph, and Dr. Skeete, members of the society. The number of cases of hydrophobia which were brought forward is noteworthy.

The society appears to have flourished for many years, 168 ordinary members were elected in the years 1783–1785, and judging from the subscriptions collected each evening it would appear that probably the attendance was often over forty, while the amount of fines exacted at each meeting from absent members or from those who had failed in their observance of the rules frequently amounted in the latter years of the century to over £5.

The Pupils' Physical Society in the early part of the century branched off from this one and still continues to flourish; it may, therefore, claim to be a descendant of one

Digitized by Google

of the oldest societies in London. The original society gradually waned as the numerous medical societies developed and finally ceased in 1852.

In 1798 a volume appeared entitled "Medical Records and Researches, Selected from the Papers of a Private Medical association." It was printed by Cox of St. Thomas-street in the Borough, and the papers were contributed or collected by Astley Cooper, William Babbington, and John Haighton, who were three out of the six presidents of the Physical Society for that year. Within the next year or so the two former were elected on the staff of Guy's Hospital, and soon became busy with practice, and no further volumes were published. It is not improbable that the Physical Society did publish some of their material, as a printing committee was elected annually, but from a passage in the life of Astley Cooper I conclude they did not publish this volume. In this Cooper published two cases of hernia of the abdominal viscera into the thorax and some observations and experiments on the occlusion of the thoracic duct. Haighton's most important paper described some experiments which he had been induced to make owing to his opinion that the fatal results of Cæsarean section might be due to the admission of air to the abdomen. He performed some laparotomies on animals with the abdomen under water, and then applied an adhesive composition to the cut edges, and outside this a bandage. He obtained complete recoveries. However, not being quite satisfied, he repeated the operations in the air and obtained equally good results, thus convincing himself that the ill results ordinarily obtained were not merely due to exposure to the air.

The Physico-Medical Society.—There is in the British Museum a copy of the laws of the Physico-Medical Society of London, established in the year 1771. We read: "In the year 1772 several medical gentlemen residing in London associated themselves for the purpose of submitting their respective opinions to the examination and correction of each other." At first the name adopted was the Philosophico-Medical Society. The volume gives the laws as revised, arranged, and amended in 1774, when this name was discarded. The council consisted of four presidents, a treasurer, two secretaries, and nine members. The society met on Monday evenings at 7 o'clock for nine months in the year; from 7 to 9 P.M. for a debate on a set subject each night, and the members dined together once a year. The annual subscription was a guinea. They possessed a library and members could borrow books. I have not been able to identify this society with any of the others, nor is it clear where they met.

The Medical Society of London (Bolt-court).—The Medical Society of London was instituted in 1773 and, according to the Medical Register of 1783, met every Tuesday evening at 7 o'clock at Crane-court, Fleet-street. It at first consisted of thirty physicians, thirty surgeons, and thirty apothecaries, and the meetings were held in the house of Dr. Lettsom, who was in every way a most liberal benefactor to the society, giving donations of money, books, and finally the premises in Bolt-court. He was practically the founder of the society. Dr. Fothergill was also a munificent donor of books. In 1784 the society was nearly wrecked by violent party disputes over the candidatureship of two of its members, Dr. Cooke and Dr. Whitehead, who was President at the time, for an appointment at the London Hospital. After 1784 two gold medals were awarded biennially for original essays, but judging by the meagreness of some of the successful essays there must often have been but little or no competition. In 1794 the attendance at the meetings was often very small, and sometimes only four members were present—as a result they tended to drift into gossip rather than business. The society somehow got under the thumb of Dr. James Simms, who succeeded in being re-elected President for over twenty years. They agreed to pay him and his wife an annuity of £30 a year, and in 1800 paid him £500 for a large number of his books. The manner in which Dr. Simms managed the society gave great offence and led to the secession of a number of members, who formed the Medico-Chirurgical Society in 1806. The society in 1850 amalgamated with the Westminster Medical Society and still flourishes at Chandos-street. Six volumes of the "Memoirs of the Medical Society of London" were issued between the years 1792 and 1805. It is clear that at first Dr. Fothergill and Dr. Lettsom were the influential members.

The Medical Society (Great Queen-street).—This medical society was instituted at the Anatomical Theatre, Great Queen-street, Lincoln's Inn Fields, on Dec. 9th, 1779. The members met every Tuesday evening at 7 o'clock from October to May. Medical news and cases were brought forward from 7 until 8 o'clock, when the dissertation for the evening was read out by the author, and afterwards by the president, paragraph by paragraph, for discussion. The president wore his hat while in the chair. Dissertations were written by each member in turn, and any member failing to write one was fined 10*s.* 6*d.* Members absent without having sent an apology were fined 2*s.* 6*d.* There are copies of the laws of this society and the list of members in the libraries of the British Museum and of the Royal Medical and Chirurgical Society, dated 1783 and 1784.

This society was started by John Sheldon in connexion with his Anatomical School at Great Queen-street. Sheldon was also surgeon to the General Medical Asylum in Welbeck-street. The society possessed a library, and awarded a diploma to members who gave proof of sufficient medical ability and had written two dissertations. The greater number of the members were practitioners, only a few being students. In 1783 the society consisted of twelve foreign and seventeen honorary members, with eighty-seven ordinary members who were required to attend the society regularly. Old members kept their names on the book when they moved into the country as corresponding members. Mr. Sheldon was perpetual president, and each year from one to three other members were also elected as presidents. Sheldon and Cruikshank, I learn from Mr. D'Arcy Power, were rival teachers under Dr. William Hunter at the Great Windmill-street School; both were teaching anatomy and both were working at the lymphatic system. Owing to some difference with Hunter, Sheldon left and started an anatomical school for himself at Great Queen-street. About the time of Hunter's death Dr. Johnson wrote to Sir Joshua Reynolds in favour of Cruikshank for the post of Professor of Anatomy, which Hunter had held at the Royal Academy, but Sheldon was elected, and retained the office till his death in 1808, when he was succeeded by Anthony Carlisle. Sheldon was a great patron of æronauts and was the first Englishman who made an experimental ascent. In 1788 he was compelled to resign his surgical appointment at Westminster owing to overwork. This medical society was evidently closely associated with his teaching and was under his control; the majority of the members, however, were practitioners. I have not been able to trace the society later than 1784; apparently it ceased when Sheldon gave up his house, and it would appear that within a few years Wilson, who had been Cruikshank's assistant, was lecturing on surgery in Great Queen-street in probably the same house. This society was a rival and opponent of Hunter's Lyceum Medicum, with which Cruikshank was connected.

The *Society for the Improvement of Medical Knowledge* was established by Dr. Foart Simmons and others in February, 1782, for the purpose of collecting useful essays and observations for publication. Dr. Simmons had studied at Edinburgh, where such societies were flourishing. He had just been appointed physician to St. Luke's Hospital, and became the most distinguished alienist physician of his day. In 1803 he was called in to attend George III. Meetings of the society were held once a fortnight, on Tuesday evenings, at Old Slaughter's Coffee-house in St. Martin's-lane, when papers were read. There were formal meetings once a quarter, when candidates were proposed at one meeting and balloted for at the next. The society consisted of sixteen members, with a president, treasurer, two secretaries, and a committee for revising and selecting papers for publication. They published two volumes of *Medical Communications* in 1784 and 1790 respectively, containing thirty-one papers. The following are among the more interesting. A Careful Post-mortem of what is obviously a case of Cancer of the Œsophagus, by John Hunter, who looked upon the condition as one of ulcer. Nothing is more striking in reading the records of this time than the lack of system in the post-mortem examinations: one or two organs which were suspected were examined, but too often no note is made as to the condition of those which had probably been the real source of the illness. Hunter often gave full and accurate reports, but rarely examined all the organs. A most remarkable case of a sword wound of the stomach which recovered is reported by Dr. Carmichael Smyth, physician to the Middlesex Hospital. The patient was fed for weeks per rectum with from four to five pints of broth daily, which was retained. Mr. Henry Watson, senior surgeon to the Westminster Hospital, proposed enterectomy for cases of

Digitized by Google

hernia in which the bowel was found to be gangrenous. He showed, by a successful operation on a dog, that by making a solid cylinder of isinglass jelly, which he inserted into the two cut ends of the intestine, they could be brought together and united by a continuous suture with a Glover's needle and thread. Dr. Willan records a case of fasting which lasted for sixty days, the man only taking water and two oranges each week.

In the library of the Royal Medical and Chirurgical Society there is a manuscript which belonged to Dr. Lettsom entitled "A Scheme for Instituting a Society under the title of the Society of Physicians of London, instituted for the Improvement of Medical Knowledge and also for building a New College of Physicians, 1782." It is somewhat uncertain whether the date is not a recent addition in another handwriting. If this refers to the same society the manuscript, I should conclude, was written by Dr. Foart Simmons; but as the writing appears to be that of an old man, and Simmons would be about thirty, it is almost certainly quite distinct. The object for the foundation of the society was to organise the Licentiates of the College together and to raise funds to build a new College of Physicians. The Licentiates included many men of the greatest ability and with the largest practices; but unless they were graduates in medicine in the universities of Oxford or Cambridge, and had, therefore, conformed to the Test Act, they could not become Fellows. They had shortly before lost an action which they had brought against the College before the Court of King's Bench, and hence the bitter feeling which is expressed. The scheme commences by stating that every member is to subscribe £50, and those whose fortunes enable them are expected to be more liberal. Public-spirited persons, particularly dissenters of different denominations, are to be applied to for assistance; the regulations included the formation of a magnificent library, but nothing seems to have come of this great scheme.

Society for the Improvement of Medical and Chirurgical Knowledge.—This society issued three volumes of Transactions between 1793 and 1812. The society was founded by John Hunter and George Fordyce, senior physician to St. Thomas's Hospital, in 1783, which is the date of delivery of the first paper, but none were published till ten years later. The society originally consisted of nine members, with power to increase up to twelve, but not beyond, and only eighteen, whose names are given in the minute book, joined during the thirty years of its existence. They met once a month at Slaughter's Coffee-house, and after dinner read and discussed the papers. Members to be eligible were required to be living in the neighbourhood so as to attend regularly, and they were required to be physicians or surgeons of five years' standing, or to be on the staff of St. Bartholomew's, St. George's, Guy's, or St. Thomas's Hospitals. It is interesting to note that the first volume of Transactions was published in 1793, the year of Hunter's death, and after 1812, when the last volume was issued, the society continued merely as a club of ten, who dined together once a month. They had been, according to their last secretary (Mr. Benjamin Brodie), a very exclusive society and finally dissolved in 1818. The minute book is now in the Library of the Royal Medical and Chirurgical Society. The chief contributors to the Transactions were John Hunter, Dr. John Hunter, physician to the army, Dr. G. Fordyce, Dr. Jenner (paper on the preparation of tartar emetic), Matthew Baillie, Everard Home, Anthony Carlisle, and John Clarke, most of whom it will be seen were Hunter's pupils. Dr. Wells was the most remarkable and influential man in the society after Hunter's death.

Hunter's communication on inflammation of the internal coat of veins is one of great importance. He pointed out that it occurred wherever there was severe inflammation in the neighbourhood of large veins, whether as the result of a compound fracture, an accident, or a surgical operation, but that it may also occur after venesection, and insists upon the importance of obtaining primary union. He points out that a thick, dry compress of linen or lint is the proper dressing for venesection or for compound fractures so as to allow dry scabbing, but that if the parts are kept moist or prevented by plasters from evaporating they always suppurate and the vein is then liable to inflame, and if so it will become occluded. If the surgeon suspects suppuration to have taken place he must keep a compress on the vein higher up. Hunter also reports one of the first cases of artificial feeding (a case of melancholia) by an œsophageal tube, which was suggested to him by a tube he was using for injecting liquids into the stomachs of animals. The difficulties might have appeared to any one but Hunter insurmountable. A probang was inserted in a fresh eelskin and tied in above and below the sponge. A slit was then made in the skin just above the sponge. The probang was passed into the stomach and a wooden pipe with a bladder attached was pushed over the probang. The food and medicine were put in the bladder and squeezed down the tube. In this way the patient was fed until he recovered. We also read in Hunter's own case-book of a patient whose pulse failed suddenly when the spermatic cord was tied during the removal of the testicle for the treatment of a large hydrocele. Hunter at once injected into the stomach with a crooked tube and syringe (such as he was in the habit of using for injecting fluids into the stomachs of animals for the purposes of experiment) volatile cordials and then laid the body before the fire, but without avail.[1]

Lyceum Medicum Londinense.—This society was established under the patronage of John Hunter and Dr. George Fordyce in January, 1785. The meetings were held every Friday evening from 8.30 P.M. to 11 P.M. between October and May. in Hunter's lecture room, which was situated between Castle-street and the east side of Leicester-square. According to Chevalier, Hunter gave them the gratuitous use of his lecture room and generally displayed for their benefit the more interesting and instructive of the additions to the museum. Among the receipts of Hunter's executors, an abstract of which was published by Dr. Finlayson.[2] I notice a sum of twenty-four guineas was received in September, 1793, from this society, but no further payment was made within the next year or so; it is not clear, therefore, for what this was paid, possibly for carpenters' or printers' work, and not for rent. The Royal College of Surgeons of England possess a copy of the rules of the society and a list of members from the foundation to the date of publication, 1792, from which we learn the following particulars. The society consisted of honorary, corresponding, and ordinary members, the latter being divided up into three classes.

The six honorary members were the following teachers: John Hunter, lecturer on Surgery in the Haymarket; George Fordyce, lecturer on Physic at Essex-street; William Saunders, lecturer on Physic at Guy's Hospital; William Osborn and Thomas Denman, lecturers on Midwifery at Leicester-square; and William Cruikshank, lecturer on Anatomy at the Hunterian Museum, Great Windmill-street; the corresponding members (21) being teachers or members of hospital staffs in the country. The ordinary members consisted of: Class 1. Those who had taken a qualification or were in practice; of these there were 78, and among the names may be noted the following: Baillie, Home, Adair, J. Clarke, Pearson, Ford, Cleghorn, Babington, James Curry, Abernethy, Astley Cooper, and Thomas Young. Class 2, which numbered 314, consisted of those who had attended a hospital and one course of lectures on Anatomy and the practice of Physic. Class 3, numbering only 7, consisted only of those who were commencing their studies. The two former were required, in turn, to read a dissertation which, on the following Friday, was read out by the President and discussed. The first hour of each meeting was devoted to the narration of medical cases, which were entered in a book, and the more important were sent to Dr. Foart Simmons to be published in his Medical Facts and Observations. The society possessed a library and presented a five-guinea gold medal annually for the best dissertation on a set subject.

Such a society was a very great educational centre, as each member was required to observe and inquire for himself; fines were inflicted on a member who left a meeting without publicly standing up and asking permission; and for each time he failed to attend the meetings until he had read a dissertation, after which he attended at his convenience. No member was allowed to leave London without writing for permission. There was an entrance fee of a guinea. Jenner, we learn, attended a meeting of this society on April 22nd, 1801, when he was admitted a Fellow.[3] But little is now known about the society; the Index Catalogue of the Surgical General Library, U.S. Army, possesses the Laws for 1798. The society had ceased by 1805 to hold any meetings. In that year Sir C. Mansfield Clarke, Sir B.

Brodie, Dr. Baillie Clarke, and a few other members of the society established the Westminster Medical Society for the purpose of promoting intercourse between students and teachers, and the members of the old society were elected honorary members. After a somewhat chequered career this society amalgamated with the Westminster Society, and later both with the Medical Society, which now flourishes.

Hunter's influence was paramount in the three following societies: (1) The Society for the Promotion of Medical and Chirurgical Knowledge, which was a small society of physicians and surgeons founded in 1783, consisting of nine or ten members, who dined together and discussed their papers, of which they published three volumes after the death of Hunter; (2) The Lyceum Medicum Londinense, a large society which met at Hunter's Museum and numbered 350 members, including, probably, all those who attended Hunter's lectures on Surgery, Cruikshank's on Anatomy, Saunders' on Physic, and Denman's on Midwifery—i.e., probably a majority of the students in London; and (3) The Physical Society, which met at Guy's Hospital and was attended by the students of the United Hospitals—Guy's and St. Thomas's—and by the practitioners in the neighbourhood. It numbered more than 200 members. It is not possible now to determine with certainty who were the founders of the latter society, but in 1783, in the earliest remaining record, we find the most influential members were pupils or friends of Hunter, who all looked up to him as the greatest living authority on all questions. Thus at this period Hunter influenced more or less directly some 500 students and practitioners, and his museum was more especially at the service of the Lyceum; the only other society was Sheldon's, which contained, however, very few students. The Lyceum, the Physical, and Sheldon's Medical Societies were not included in the Medical Register for 1783, probably because they were not limited to practitioners and were looked upon as merely part of the educational machinery of the metropolis. It is not to be wondered at, that twenty years later, Hunter's were the views accepted by the leaders of surgery in London and that he had revolutionised the studies of surgeons; and there can be no question that the change had largely been brought about by means of these societies. When, after years of isolation, the schools of London and Paris compared notes at the end of the war it was found that the English surgeons were far ahead of their *confrères*, thanks to Hunter, but that the converse was the case with regard to medicine.

The Society of Physicians.—Dr. S. Foart Simmons, who compiled the Medical Register of the last century, which was issued in the years 1779, 1780, and 1783, giving a list of all the medical men and of the societies of Europe, also edited the *London Medical Journal* for a society of physicians. Eleven volumes were issued between 1781 to 1790, and the publication was continued as *Medical Facts and Observations* from the year 1791 for six volumes.[4] The *Journal* was published monthly and consisted of reviews of all the new European medical books, of original papers and of medical news, being on the same lines as the medical and philosophical commentaries of Edinburgh, and together they give us the best epitome of the current medical opinions of the time. I have not been able to learn more about this society beyond what is stated in the first volume. It appears that the society had occasionally met together to converse on medical subjects, and at the instigation of Dr. Simmons, who undertook to act as editor, they agreed to set on foot this monthly publication.

Not much can be learnt of the Middlesex Hospital students' medical society, which dates back to 1774, but of which records have not been preserved. The students appear to have met twice a week in the physicians' room. The Abernethian Society of St. Bartholomew's Hospital commenced at the end of the century.

In bringing before you this evening these remarks about Hunter and the history of the medical societies of London, I trust we all realise how great a debt we owe to the Hunters (William and John) and to John Sheldon for instituting debating societies for the purposes of medical education. We can afford now to read with amusement a pamphlet which is entitled, "Reflexions on a Letter addressed to the Governors of St. George's Hospital by John Hunter in 1792." After abusing Hunter for his lack of education, &c., the writer says: "Your disputing societies, several varieties of lectures in a day, and a squint at an operation are the fashionable attendances of the modern student. Since the Medical Tea-sipping Society was commenced mankind has been classed to view the wonders of your museum and the world indulged with a volume of your notions at the common price. It is ridiculous to observe how this tea-kettle invitation has spread. An apothecary may now take his tea gratis and have a game of whist for only the price of the cards every evening in the week, if he keeps a regular list of the bread-and-butter manufactories."

[4] There are seven volumes in three in Guy's Hospital Library.

GLEANINGS FROM SURGICAL PRACTICE.

BY THOMAS BRYANT, M.CH., F.R.C.S. ENG. & IREL.,

CONSULTING SURGEON TO GUY'S HOSPITAL; PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

VI.[1]—ON OBSTRUCTED ARTERIES.

EVERY practitioner of medicine or surgery is familiar with the fact that an artery in its continuity may become obstructed, although when this condition is discovered there may be some difficulty in making out its precise cause. Every student of pathology and observant visitor to our college and hospital museums will know that this obstruction, partial or complete, may be brought about by diverse causes, and bedside experience will soon teach him that the results of arterial obstruction are very variable. As time passes and experience increases he will have learnt that an artery may become the seat of inflammation, ulceration, or sloughing, either as a result of local injury or from the extension of inflammation from some neighbouring tissues, and be led to appreciate the fact that any action, whether called inflammatory or otherwise, which alters the nutrition of the inner coats of an artery may help to encourage the coagulation of the blood in that artery, and as a consequence bring about thrombosis in the vessels at the part affected with all its attendant dangers. He will, moreover, have been led to recognise that chronic changes may so insidiously go on in an artery as to bring about a narrowing of its lumen even to its closure, which one pathologist will describe as being due to a congenital condition and another to a form of local arteritis called obliterative.

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of Nov. 2nd and 9th, Dec. 7th, 1895, Jan. 11th, and Feb. 8th, 1896, respectively.

The following two cases are striking examples of this condition and in both an aortic aneurysm existed. In one, a young patient, the aneurysm was situated below the contracted orifice of the subclavian artery; in the other, an old patient, the arch of the aorta with the innominate artery was its seat. In neither of the cases was the obstruction recognised during life; its true cause was made out only after death.

CASE 1. *Aneurysm of the aorta giving rise to laryngeal symptoms; apnœa and sudden death; almost complete closure of the orifice of the left subclavian artery.*—A healthy-looking, sensible, married, childless woman aged twenty-two years came under my care at Guy's Hospital on July 5th, 1869, suffering from dyspnœa which came on at uncertain intervals and had existed for two years. Her trouble was supposed to be laryngeal. When admitted she was tranquil and apparently well, but she dreaded an attack, for she felt sure she would die in one. On a careful general examination, as nothing wrong could be made out except an absence of pulsation in the arteries of the left arm, which was otherwise normal in size and in temperature, the question of her dismissal from the hospital was raised, but she seemed so truthful and alarmed at her condition that it was arranged to keep her for observation. Within twenty-four hours of her admission and at night an attack of dyspnœa came on which so speedily became intense and threatened death that tracheotomy was performed, but as the tube was being introduced death ensued. At the post-mortem examination, made by Dr. Moxon, an aneurysm the size of a plum was found to be pressing upon the left side of the trachea and left bronchus so as to flatten both. It sprang from the right side of the descending aorta about one inch and a half below the orifice of the left subclavian artery, and it had an oval mouth which measured half an inch by three-fourths of an inch. The arteries generally were healthy, but marked by many semi-cartilaginous patches of thickening, one having an atheromatous centre. The left subclavian artery was almost entirely closed at its mouth by constriction and thickening. The ovaries were shrivelled and the Fallopian tubes were closed at their ends, bent down and adherent to the ovaries. The neck of the uterus was abraded and its body was large and flaccid. The kidneys were natural.

CASE 2. *Aneurysm of the aorta and innominate artery; ligature of the right common carotid; death on the fourteenth day; obliteration of the origin of the left subclavian artery.*—A man aged fifty-eight years came under my care in January, 1877, with a large aortic and innominate aneurysm which was pressing upon the trachea and œsophagus and giving rise to great pain and loss of voice. It had been coming for about a year. It was reported at the time that the radial pulse of the right or affected side was much stronger than that on the left and that the pulses of the left arm were very feeble. I applied a ligature to the right common carotid and no difficulties were experienced; indeed, everything seemed to be going on well and the patient expressed himself as being greatly relieved, but on the twelfth day he sank. At the necropsy, as made by Dr. Moxon, the aneurysm was found as described and the parts connected with the operation were all healthy.[2] The origin of the left subclavian artery was obliterated. The obliterated part was not converted into a cord, but was longitudinally wrinkled as if incompletely filled with something. On opening this part it was found to contain some fibro-cellular-looking material of loose texture adherent in part to the wall of the artery and yet pretty easily separable in parts to show that it was quite a separate material to the arterial wall. It might have been organised clot, but if so it is difficult to explain the condition of the orifice of the subclavian—a mere pouch without a trace of aperture into the artery. The vessels were all normal which arose from it beyond the obliterated spot except one very large trunk half as large as the subclavian itself, which must have been from its position the inferior thyroid. The left internal jugular vein, with the left subclavian and axillary veins, were plugged by recent adherent thrombus. The left innominate vein was free. The viscera were healthy.

The most common pathological changes met with in arteries are those known as the calcareous and atheromatous; through the former the vessels become more or less rigid and inelastic, and through the latter the formation of most aneurysms which are not of traumatic origin is to be ascribed. At the present moment, however, what is of special interest is as to how these changes in the coats of an artery may lead up to its occlusion. To this aspect of the matter I shall devote a few lines. It should be understood that an artery the subject of either of these two affections mentioned may become occluded in at least two ways. In the one case, at the seat of either some calcareous deposit or atheromatous ulcer as it is called a clot may form, the fibrin from the blood as it flows onward being as it were whipped by the rough surface of the diseased artery into a clot, which enlarges so as to form a thrombus big enough to occlude the artery. In the other case the clot is formed in the same way, but instead of enlarging where it was formed it becomes dislodged by the blood force and is carried forward in its stream along the narrowing arterial channels to some more or less distant position past which it is too large to travel, and there as an "embolus" becomes impacted so as to occlude the artery, the favourite position of this embolic plugging being the bifurcation of a vessel. In some cases, again, portions of calcareous or atheromatous tissue doubtless help to form the clot and in small vessels even to form the embolus. Certain examples of senile gangrene are unquestionably due to this cause.

All examples of embolic plugging are not, however, to be thus explained. Some are associated with certain blood conditions found in fevers, such as scarlet fever. I have had three cases of this kind in young women under my care in which the popliteal artery was the vessel plugged. In all gangrene followed as a consequence of the obstruction, and in all amputation was performed, with a good result in two; the third, a girl aged fifteen years, was too feeble to recover. In the majority of cases of embolic arterial obstruction heart disease is its true cause. In some the heart affection is of an acute nature, in others of a chronic. What is known as septic or malignant endocarditis is the most common. The embolus in all these cases is of a fibrinous nature; it forms upon one of the valves and is washed off by the blood current and floated downwards to where some impediment to its progress is met with and thus blocks the vessel.

In another class of cases the obstruction is brought about by traumatism, and to this I particularly wish to draw attention in a subsequent paper, for examples of this kind come directly under the notice of the surgeon, whereas those which are included in the former division only come into his hands in their later stages, when gangrene is either threatened or present.

(To be continued.)

A CONTRIBUTION TO THE SURGERY OF THE URETER.

BY J. BLAND SUTTON, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

THE ureter is practically a muscle traversed by a channel lined with epithelium. At its lower end the muscle-tissue of the ureter is directly continuous with that of the bladder. It has been determined by actual observation that rhythmical waves of peristaltic contraction occur in the ureter, the waves passing invariably from the kidney to the bladder. As these contractions of the ureter arise much in the same way as those in the muscular substance of the heart we may with Foster speak of them as "beats." These spontaneous movements or beats "are subordinated to the flow of urine into the pelvis; the more active the secretion of urine the more frequent and vigorous are the beats of the pelvis and the ureter." It is very fallacious to simply regard the ureter as a passive conduit; urine is conveyed along it on the same principle that fluid is conducted into the stomach by the œsophagus. The rhythm and power of the ureteric beat may be best studied in adult individuals with exstrophy of the bladder. When urine is being abundantly secreted a jet of fluid, sometimes 5 centimetres high, will issue from each ureteric orifice at intervals of a few seconds. Occasionally the jets from the two openings are synchronous, sometimes alternate, but, as a rule, independent in time and variable in force. When the flow is less abundant the jet appears with diminished regularity and with longer intervals.

Great and unusual suffering sometimes results from what may be termed exalted action of a ureter, as the following case demonstrates:—

In August, 1892, I saw a married woman twenty-eight years

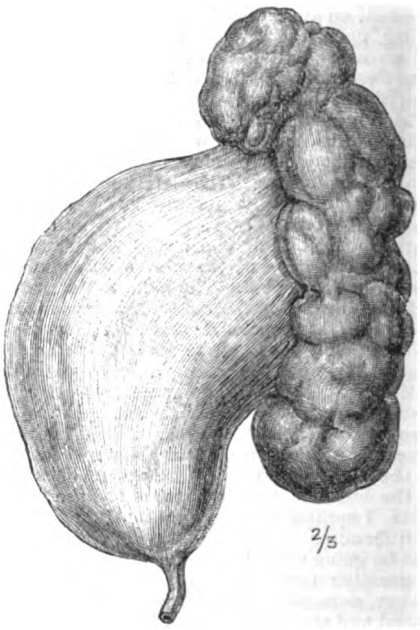
Digitized by Google

of age for chronic disease of the Fallopian tubes. She was sterile and had been treated for several years by rest and drugs. Her condition had become so serious that it was necessary to attempt the removal of the uterine appendages. At the operation the Fallopian tubes were found enlarged with a diameter of 2 centimetres and firmly adherent to the pelvic floor. The left tube and a part of the ovary were detached and ligatured. When the right appendages were released and drawn into the wound a coil of ileum was found adherent to the tube. The gut was gently detached; it was then discovered that the adherent ileum covered a circular perforation in a flexure of the tube. The ovary and tube were removed, the pedicle being secured with silk. Convalescence was soon complete and the patient spent the winter months in the south of England, returning to town in May, 1893. She now began to suffer from increased frequency of micturition and I began to suspect that the stump on the right side was giving trouble, and on vaginal examination a tender lump could be felt to the right of the cervix. The trouble with the bladder increased and became serious; on two occasions there was a definite rigor followed by a temperature of 102° F., so I determined to puncture the swelling through the vagina with the hope of finding pus. This was done, but no pus was found. Two days later the patient complained of a profuse watery vaginal discharge, which I soon satisfied myself was urine. Records were kept of the amount of urine discharged from the bladder and of that which escaped from the vagina, and it was found that they were equal. It was noteworthy that coincidently with the establishment of the urinary fistula the pain and discomfort at once disappeared. It was ascertained that each time the patient passed urine its amount measured with extraordinary exactitude two ounces. Fourteen days after the fistula was established it was resolved to investigate the bladder under anæsthesia in order to determine the situation of the fistula and Mr. Buckston Browne gave me the benefit of his advice. On examining the vagina a rounded aperture was detected in the fornix to the right of the cervix. Milk injected into the bladder was retained and did not escape by the fistula. At this consultation we ascertained two facts: (1) that the fistula was ureteric; and (2) that the bladder was contracted and would not hold more than two ounces of fluid. We also were hopeful that the fistula would close and decided to wait for this event. Ten days later the fistula showed signs of closing and a few days later closed for ever. Coincident with the closure of the fistula micturition became painful and urgent, the bladder discharging with great exactitude two ounces of urine, as shown by the fact that two ounces of urine were passed at 6.25 A.M., at 8.40 A.M., at 10.30 A.M., at 11.10 A.M., at 12.40 P.M., at 1.45 P.M., and at 2.50 P.M.; one ounce and a half at 3.25 P.M., and two ounces at 4.40 P.M. and at 6.20 P.M. The clinical facts enabled us to make the following deductions: 1. The right ureter was entangled in inflammatory tissue in that part of its course where it runs between the layers of the broad ligament (mesometrium). 2. This implication of the ureter near its vesical termination teased the bladder and induced tonic contraction of its muscle tissue. These deductions were explained to the patient and her husband and it was pointed out that if the symptoms did not abate we should probably deem it necessary to remove the right kidney. The trouble increased, and after a careful consideration of the case with Mr. Buckston Browne nephrectomy was decided upon and the right kidney was removed in June, 1893. The organ was quite healthy. The results of the operation were admirable. The dysury ceased immediately, the excessive vesical contraction began to yield, and the capacity of the bladder increased in a few days to four ounces. Three weeks after the removal of the kidney the wound was healed and the bladder would hold without discomfort ten ounces of urine, and a few weeks later the patient wrote that she had no trouble with the bladder, but that a sinus had formed at the lower end of the scar left after the oöphorectomy. Some months later a silk ligature escaped and the sinus closed, and she has since remained in vigorous health. She menstruates regularly and at times this is accompanied by pain. The persistence of this function is due to the fact that I was unable to remove completely the left ovary. At the present date the patient is in excellent health.

The next case illustrates the suffering which is occasioned by an inadequate ureter. In 1894 Mr. J. J. Clarke of Walthamstow placed under my care a married but sterile woman forty-four years of age on account of abdominal pain. When she first came under observation a painful swelling was easily made out in the left iliac fossa, resembling in some points an ovarian tumour. After resting in the hospital this swelling disappeared, but an ill-defined mass could be made out on each side of the uterus. The patient complained most of a dragging pain in the left loin with frequent attacks of acute pain resembling renal colic. She had suffered from pain of this kind at intervals for twenty-five years, but it had increased in severity during the last year and caused her so much suffering that she was anxious for relief. On physical examination the kidney was not perceptible on either side, although the woman was very thin. Observations were made on the urine daily, but no defects in quantity or quality were detected for many days. One morning after a night characterised by more than usual pain the urine was opalescent and on microscopic examination yielded pus. I decided to explore this kidney. It was examined through an incision in the left linea semilunaris and found to be a flaccid sac; the right kidney was normal in size and texture; the ovaries were cystic and as big as hen's eggs, but free from adhesions. The abdominal incision was closed and the left kidney removed through an incision in the loin. Next day the pain had ceased. Recovery was rapid and complete.

The kidney is interesting; the cortex (see Fig. 1) is represented by a lobulated sac containing a small amount of secreting tissue; the infundibula and the pelvis form a thin-walled bag opening suddenly at what corresponds to the ureteric strait into a very narrow ureter, indeed, the canal of this ureter is narrower than that of a fœtus at term. When fresh the dilated pelvis had a velvet-like appearance, and it seems to me probable that inspissated inflammatory exudation from time to time plugged the orifice of this inadequate ureter and led to distension of the pelvis. The transit of the obstructing plug induced exalted action of the muscle fibre of the ureter and consequent cramp or renal colic. It seems to me probable that we have to deal with an unusual example of congenital hydronephrosis; the patient was certain that she had suffered from "the pains" in her side for twenty-five years. This view receives support from the lobulated condition of the vestige of the renal cortex and the extreme thinness of the ureter.

FIG. 1.



Hydronephrosis associated with an inadequate ureter.

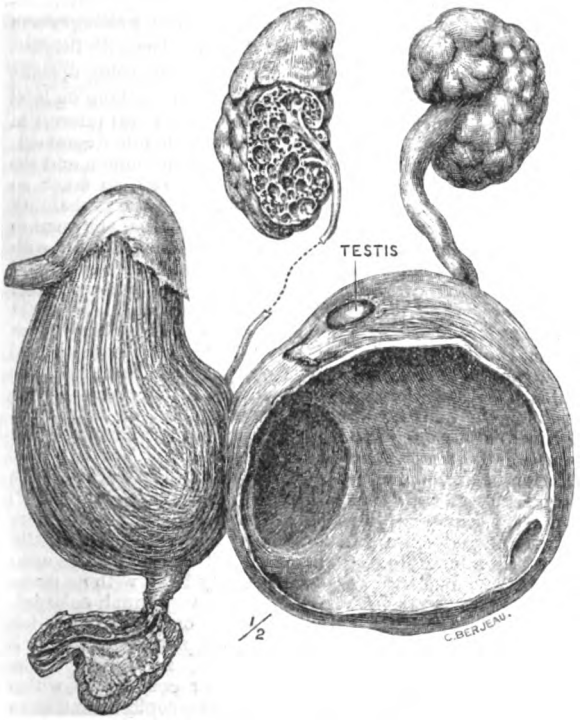
It is an interesting and, from a diagnostic point of view, important fact that hydronephrosis is often accompanied by increased frequency of micturition. The cause of this was never clear to me until my experience recorded in the first case. Thus it would appear that when the "beat" of the ureter becomes exaggerated the muscular contraction is not confined to the ureter but involves that of the bladder, producing what we usually call vesical irritability, but when

Digitized by Google

it occurs in a voluntary muscle we speak of it as clonic contraction.

The third case forms a striking contrast to the "inadequate ureter" we have just considered. At the kind request of Dr. Chapman Grigg, Mr. Stabb was good enough to preserve for me a fœtus born at nearly full time with great enlargement of the abdomen due to some abnormal condition of the urinary organs. On dissection it was found that the fœtus had no anus and the rectum ended blindly on the back of the

FIG. 2.



Hypertrophied bladder, dilated ureter, and hydronephrotic and cystic kidneys from a fœtus with imperforate urethra.

bladder. The penis and scrotum were normal, but the urethra ended at the bulb; from that point to the bladder it was impervious. The bladder, as shown in Fig. 2, was distended and its walls greatly hypertrophied, the muscular fasciculi standing out as thick strands. Connected with the left side of the bladder is a large sacculus capable of holding 300 c.c. of fluid; the left ureter opens into this sacculus by a valvular orifice. The ureter itself is dilated throughout as well as the renal pelvis. The sacculus communicates with the vesical cavity by an orifice 3 centimetres in diameter. A careful study of the relations of the sacculus proves that it is an enormous local dilatation of the ureter and as it enlarged it carried on its crest the testis; the spermatic vessels were seen in the fresh condition of the specimen stretched across its wall. The right kidney is a congeries of cysts—an example of the condition known as congenital cystic kidney. The ureter is a thin narrow thread.

Although this specimen is devoid of what is commonly called practical interest it has, nevertheless, importance of another kind. First of all, it indicates that many specimens which have been loosely described as bifid bladders were probably of the same character as this. Some specimens described as bifid bladders are due to dilatation of the urachus (allantoic cysts), and others reported as examples of lateral bifidity of the bladder or congenital diverticulum of the bladder were in all probability, as in my specimen, enlargement of the vesical end of the ureter. It is instructive, also, to find a hydronephrotic kidney on one side and congenital cystic kidney on the other. This form of cystic kidney has long puzzled pathologists, and its association with an imperforate urethra must lead to a reconsideration of some views held in regard to its causation.

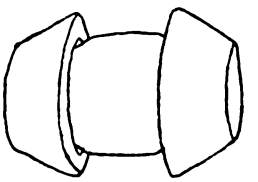
Queen Anne-street, W.

A SUGGESTION FOR INTESTINAL ANASTOMOSIS.

BY J. JACKSON CLARKE, M.B. LOND., F.R.C.S. ENG.,
ASSISTANT-SURGEON TO THE NORTH-WEST LONDON HOSPITAL, PATHOLOGIST TO ST. MARY'S HOSPITAL.

THOUGH careful stitching would appear to be the best method of reuniting divided intestine, it is common knowledge that in many cases the condition of the patient is such that any prolonged operation is out of the question, and in such cases some of the many ingenious mechanical devices invented for the purpose have to be called in requisition. In venturing to suggest an addition to the already formidable array of such instruments I naturally feel some diffidence, but I am encouraged by the reflection that, as far as I am aware, the principle of the apparatus to which I would draw attention has not been previously employed. The most ingenious and expeditious mechanical method of instrumental anastomosis is that devised by Murphy, whose "button" has no doubt saved many lives, and some of the successful cases have been treated at the hospital at which I was trained. I have, however, been called to make necropsies in a few cases in which the issue has been fatal, and in two of them I found that the wall of the gut had sloughed where it lay over the rim of the metal diaphragm which is pressed by a spring against the double layer of bowel. In the instrument which I have devised the pressure is made by indiarubber rings the edges of which are rounded off. In Fig. 1 is shown

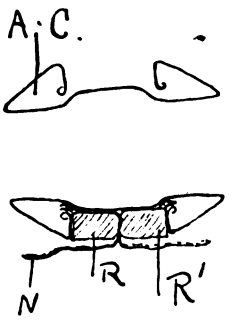
FIG. 1.



Outline sketch of the bobbin (natural size).

the size of the instrument as designed for small intestine; for large intestine an additional quarter of an inch in diameter could be obtained. Fig. 2 represents the bobbin as seen in section. The chamber AC could be used to contain some mild antiseptic. In the lower part of Fig. 2 the rubber rings are shown with the

FIG. 2.



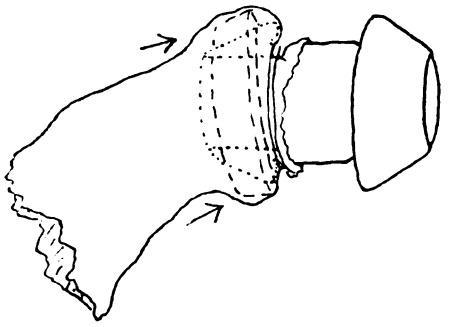
Longitudinal section of the bobbin, the intestine (N), and india-rubber rings (R and R') shown in section below.

bowel *in situ*. Both have the same diameter as the smaller part of the bobbin—i.e., half an inch. They are cut so that when stretched to the diameter of the barrel of the empty bobbin their depth just brings them flush with the lips of the larger ends of the bobbin. The mesial edges, both inner

Digitized by Google

and outer, of the rubber bands are slightly rounded off. One band (B) is half as wide as the barrel, and the other (B′) is cut obliquely, so that at its outer edge it is $\frac{1}{32}$ in. wider than half the length of the barrel. The mode of making the anastomosis is shown in Fig. 3. One of the rubber rings

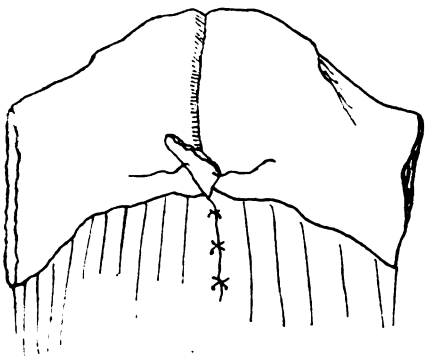
FIG. 3.



Showing the mode of pushing the ring into position after the bowel has been secured to the bobbin by a purse-string ligature. Only one ring is shown, although both are pushed on at the same time.

is lubricated with oil or soap and is inserted into one end of the gut, and then a purse-string stitch is run close to the border of the intestine and securely tied over the narrow neck of the barrel. The other end of the gut is treated in the same way, then the rings are easily pushed (by the fingers of the operator pressing through the gut) over the ends of the bobbin on to the barrel, and thus a secure anastomosis is effected. The redundant part of the mesentery may be drawn into two triangular folds, one on each side of the bowel, and fixed, as shown in Fig. 4.

FIG. 4.



The appearance of the anastomosis when completed.

I have tried the process on both thin atrophic and thick œdematous bowel in the cadaver and found it work well, the anastomosis being effected in six minutes. After the anastomosed bowel had been for some days on the instrument in weak formalin solution the part of the bowel between the rubber tubes was found to be thin and papery, whilst the rest of the bowel was thick and succulent. The slight wedge-shape of the rings would seem to secure sufficient pressure to cause sloughing. I hope soon to acquire the power to test the apparatus on some suitable quadruped. Its advantages would appear to be as follows. It does away with the sharp cutting rim of Murphy's button, it is much lighter (if made of aluminium it would be extremely light), it has a much larger lumen (and thus would cause less obstruction and allow more rest to the bowel), its ends are more tapering, the antiseptic chamber could be used to contain a weak glycerin-gelatin carbolic mixture which by osmosis would keep in check too rapid sloughing at the line of separation, and it is simpler and cheaper. The instrument has been very skilfully made for me by Messrs. Meyer and Meltzer.

Old Cavendish-street.

LEUCOCYTHÆMIA AND ITS TREATMENT.

BY RICHARD J. COWEN, L.R.C.P., L.R.C.S. IREL.

ON July 1st, 1895, a married woman aged twenty-eight years was brought to me for treatment. In appearance she was exceedingly pale, with dark areolas around the eyes; she seemed to suffer from great difficulty of breathing in walking and much lassitude. She described her ailment and its history as follows. Some two months ago she noticed that she was getting weaker, and her friends were constantly telling her how bad she was looking; her appetite was getting worse every day, and even the sight of food filled her with disgust. She noticed that she had increased difficulty in going upstairs because she "panted so much," and even walking on level ground caused her the same trouble. She lost all interest in her daily work and her spirits were very much depressed. She suffered a good deal from pains in the abdomen and she found her waist had increased in size, indeed, so much so that her neighbours congratulated her upon the probability of an accession to her family. About this time she went to see a medical man, and was treated, she believes, with arsenic and iron, but under his treatment she found herself rapidly getting worse. Occasionally she noticed large bruises appearing on her legs and arms and she could not imagine how she got them. Her family history, as far as I could ascertain it, was good, her parents and grandparents being very healthy people. She had two children. She had never suffered from any severe illness and had no extraordinary worries of any kind. The menses were regular in period but not in quantity. Her pulse was 60, flabby and weak when at rest, but the least exertion or excitement made it irregular and fluttering. The temperature in the axilla was 97·5° F. and in the mouth 97·7°. The heart sounds were feeble; the second sound was very sharp. A pulmonic systolic murmur could be distinctly heard and a loud blowing under the left clavicle. The urine was small in quantity, of specific gravity 1012, with no traces of albumin or sugar. The abdomen was very much enlarged, hard, and tense, and a little tenderness on pressure was felt in the left hypogastric space. The spleen could be felt extending quite across the abdomen, its upper border reaching under the ribs and its lower coming to within three inches of the pubic arch. The microscopic examination of the blood showed an enormous preponderance of the white corpuscles and an abnormally small quantity of the red and white taken together. Many of the red appearing in the field seemed to be undergoing degeneration, many were granulated, while others had a broken and irregular contour. The patient lived in rather close and dark rooms. She suffered from headaches and constipation a good deal, seemed to have lost all hope of recovery, and was in a very despondent condition. There could be little doubt that the woman was suffering from leucocythæmia, though the sex and history of her case were somewhat unusual. She presented in a marked degree the dulled and enfeebled intellect so common to all affections of the blood. Indeed, I have noticed in a large number of anæmic cases that depression, lassitude, slowness of thought, and disinclination to mental work are amongst the earliest symptoms noticeable, appearing long before any pallor of the mucous membranes can be detected and even before there is any recognisable change in the appearance of the blood under the microscope. In nine cases out of ten such a train of symptoms will be found to precede disorders of the blood of an anæmic character.

The small quantity of iron in the body in health and the very minute deficiency in what we call anæmia, the rapid but too often short-lived effect of the administration of the metal, would seem to suggest that we have in these cases to treat an affection of which the poverty of the blood is only a symptom and not a cause. It has been proved by Bequerel that where two fluids are separated by an animal septum they form an electrical couplet in which the surfaces of the septum form the positive and negative poles, consequently that the tissue cells act as galvanic batteries, from which, according to the nature of the surrounding fluids, a certain amount of electrical action results. It has been found that the internal and external surfaces of the capillaries act very markedly in this manner, while the peculiar distribution of the axis cylinders of the nerve fibres around the capillary walls would suggest the idea that at

Digitized by Google

least one of their functions was to conduct away the current. For many years it was believed that the oxygen-carrying function of the blood was solely for the purpose of providing oxygen to combine with the carbon of the tissues, and so, by enabling a true combustion to be maintained, provide for the production of the necessary bodily heat; but the discovery that the amount of oxygen absorbed by a working muscle was not nearly accounted for by the amount excreted of CO_2, and that the power of such muscle was much greater in an atmosphere of oxygen than in any other, struck a very heavy blow at this theory, and no very satisfactory one has been since advanced. It is just conceivable that one of the most important functions of the blood is to act as a *depolarising* fluid, to furnish a constant available supply of loosely combined oxygen to absorb the hydrogen resulting from the electrical action which would first interfere with and ultimately stop all current. Looking at it from this point of view a more perfect arrangement could not be devised; a circle of fluid containing a substance—hæmoglobin—capable of rapidly and very loosely combining with oxygen afforded at one part of its journey every facility for absorbing oxygen from the atmosphere and throughout brought most intimately into contact with the tissue cells. Were it possible to construct a galvanic cell on this principle perfection would be attained. Presuming, then, that this is one of the functions of the blood it can be easily imagined how grave and far-reaching would be the effect of any impairment of this polarising property; there can be no doubt that a train of symptoms identical with those observed in the anæmic states would be brought about, the most marked naturally being those indicating impairment of nervous energy. From a long course of experiments I have made, I have come to the conclusion that the blood of anæmic patients, that is, those suffering from idiopathic anæmia and more especially leucocythæmia, differs from healthy blood in the fact that the hæmoglobin is in a different chemical state. It does not combine as readily with oxygen or with the same *quantity* as that in normal blood. Whether this is due to the formation of a lower oxide or whether a part of the hæmoglobin does not enter into combination at all is a matter for further experiment. It occurred to me, however, that if oxygen in its allotropic form as ozone was brought into contact with the corpuscles, its very powerful oxidising properties would do much to render the oxidation of the hæmoglobin more complete, thus giving the system time and energy to resume the proper formation of the red corpuscles and their contents, as for many reasons it is extremely probable that the excessive formation of the white corpuscles in these diseases is due to the failure of the red to fulfil their most important function. It is not, perhaps, quite correct to speak of the formation of the white corpuscles as being excessive, for the reason of their presence in such large numbers as compared to the red is more possibly because of their excessive *survival* than formation. In most cases of anæmia where an opportunity occurred for making a post-mortem examination the liver was found to contain large quantities of iron and débris of red corpuscles. Now as the liver acts as a kind of sentinel for the blood, working to destroy and expel unauthorised constituents, the probable reasons for the presence of such in this organ is that the composition of these corpuscles was so abnormal that the liver was unable to recognise them as fit to fulfil their duties and consequently destroyed them with a view to completely expelling them from the organism. As the formation or preservation of the white corpuscles is not interfered with this would abundantly account for the enormous preponderance of these. In this we have also the reason that the administration of iron has in ordinary anæmic cases such a good but short-lived effect, while in many cases the absolutely injurious effect of iron may be accounted for by the extra burden thrown on the liver.

With the object of carrying out treatment on these lines I commenced to administer ozonised air as an inhalant for fifteen minutes daily to the patient. I used a modification of Andreoli's apparatus for the purpose; in this a stream of air is driven over an arrangement of vacuum tubes surrounded by serrated and flattened wire and connected up to the electrodes of a powerful induction coil worked by eight quart bichromate batteries. At least 75 per cent. of the oxygen in the air is ozonised by the enormous number and rapidity of the discharges taking place from the large number of points surrounding the tubes. The air, after being ozonised, passes into a mask covering the mouth and nose of the patient and was inhaled. The patient had considerable difficulty in breathing, at first owing to the large amount of ozone contained, but the oppression and giddiness disappeared after the first two or three sittings completely. After seven days she volunteered the statement that "her appetite had greatly improved" and that she looked forward to "taking the gas," as she could eat such a good meal when she got home. Microscopic examination of her blood at this stage showed a diminished number of white corpuscles and a total absence of the degenerated red ones seen before. Her spirits were much better, she had lost her headache, and the pain in her abdomen was markedly better. I now increased the time of inhalation to twenty minutes daily. After a fortnight's treatment the red corpuscles had risen from 40 to 60 per cent., the white had greatly diminished in number, and the circumference of her waist three inches above the umbilicus had decreased one and a half inches. She was able to walk better and could take her food with relish. Her bowels now acted regularly. From this time she progressed rapidly, and at the end of a month she had a healthy colour both on the skin and the mucous membranes; she could run upstairs quickly without the previous distressing difficulty in breathing. The deep yellow colour of her skin, which was one of the most marked symptoms of the earlier stages of her disease, was now entirely gone; in fact, to all appearances the woman was in good health. Examination of the blood showed normal conditions, no excess of the white, no signs of degeneration in the red, the characteristic rouleau forming as usual. Her spleen had diminished to about one-half its previous size and she was able to wear the same clothes which fitted her before her illness. She now came for the inhalations every third day only, and three months from the time of commencing treatment I discontinued them, considering her to be quite cured. At the present time she presents a thoroughly healthy appearance, and with the exception of a somewhat large spleen shows no symptoms of ill-health. During the treatment she took no medicine of any kind except an occasional seidlitz powder and made no change in either food or habits. The very remarkable success of the ozone treatment in this case led me to try it in other diseases in which an abnormality in the quantity or quality of the blood was a prominent symptom, and I have had some very remarkable and encouraging results.

THE SCOPE AND VALUE OF ELECTRICITY IN MEDICINE.[1]

BY W. S. HEDLEY, M.D. EDIN.,

MEDICAL OFFICER IN CHARGE OF THE ELECTRO-THERAPEUTIC DEPARTMENT OF THE LONDON HOSPITAL.

[HAVING shown shadowgraphs[2] and explained in connexion therewith something of the nature of electrical discharges in vacuum tubes Dr. Hedley remarked that without much knowledge of photography and without any knowledge of electricity it is not difficult to imitate Professor Roentgen's results, and that already the enterprising photographer had begun to work the process commercially. It was, in fact, fast passing out of the experimental stage, and apart from other and perhaps more important bearings the "new radiation" could never lose its interest for the medical man, even on the one ground alone that it had already afforded many a useful glimpse into the interior darkness of that complex mechanism with which it is his province to deal. The subject of the address was then proceeded with.]

The electrical history of the last ten years is, as all the world knows, a history of growing knowledge and of great achievement. Medicine, profiting by the one and by the other, has begun to aim at some exactness in its electrical procedure and to demand that any sound system of electro-therapeutics be based on the principles of electrical as well

[1] Abstract of a paper read before the Medical Society of the London Hospital on March 12th.

[2] One of these showed the hand of a patient of the hospital who had broken a brad-awl in an attempt to force it into its handle. It injured the hand, but the man felt sure that none of the pieces had entered. The whole hand was much swollen, but there was no direct evidence of any foreign body. The shadowgraph, however, clearly showed two (metallic?) bodies lying across the metacarpo-phalangeal articulation of the middle finger.

Digitized by Google

as of medical knowledge. During the same period the history of medical electricity itself has not been uneventful. It is notable for the appearance of more than one memorable book. Amongst these the works of Erb and of de Watteville stand out as the first systematic and successful attempts to bring electro-therapeutics into line with exact science. The introduction of the milliampèremeter, the voltmeter, the rheostat, and other instruments of precision marked this new departure. Another era not long entered on is now in progress. It is characterised by an increased attention to electrical physics as the only sure foundation for electro-therapeutics. There are also other signs of the times. A more formal recognition by the chief metropolitan hospitals, the existence of such societies as the American Electro-Therapeutic Association and of the Société Française d'Électrothérapie, the development of a special literature, and an increasing study amongst medical men of the physics of electricity are all evidence that electro-therapeutics is beginning to organise and to assert itself. The medical man, taking advantage of recent progress in other branches of applied electricity and of the public supply currents that pass his door (and this I hope will also shortly be true of the London Hospital), finds himself in possession, not only of an improved instrumentation and a fast increasing knowledge of electrical phenomena, but has at command undreamed-of sources of electrical supply of unlimited usefulness and of novel power. From the lead of a 16-candle lamp he helps himself to an ever-ready supply of electrical energy, either of a continuous or of an alternating kind. The former furnishes a current which will do for him all that the uniform flow of the galvanic cell can accomplish. Passing the same current through a coil he obtains that dissymmetrical alternating current universally familiar as the current of the medical induction apparatus. Still availing himself of the same supply, he heats his cautery, lights an exploring lamp or charges his accumulators, or passing the current through a motor he drives his static machine or actuates his therapeutic alternator. The latter can in its turn be arranged to supply a current having all the smoothness and other qualities of that known as sinusoidal, with its rapidity, its electro-motive force, and even the shape of its electro-motive force curve under absolute control. If the current that comes to his door in the street mains be an alternating one he passes it through a transformer to apply it to the body to electrise his water bath or to heat his cautery. He is thus supplied with an alternating current of a symmetrical, although not of a strictly sinusoidal, character, whose therapeutic usefulness is fully proved. In that form of oscillating current known as the "static-induced" he finds another modern current and the most efficient method of inducing powerful and painless muscular contraction. Still more recently he begins to turn his attention to those currents of great frequency and high potential whose phenomena are a revelation to the scientific mind and whose effects open out new fields of physiological research and point to endless therapeutic possibilities.

Realising the rapidity of progress he recalls the coarse instrumentation and crude procedure of a comparatively recent past, when an unmeasured current was "dabbed" on to the body at the end of a couple of sponges, and it was orthodox practice to administer faradaic torture by means of a couple of metal cylinders grasped by the patient. In those days—and they are not long ago—the one end and aim of electrisation was to induce muscular contraction. This idea still survives in the popular mind, in the electricity of the "trained nurse" and of the "medical electrician." Nor is it quite confined to these. There is still the echo of a voice from high places proclaiming the doctrine that the only object of electrising a paralysed muscle is to keep that muscle exercised pending the return of voluntary power. Such a proposition conveys, in my opinion, no adequate idea of the properties and uses of an electric current. Modern practice covers a far wider field than this. Besides a purely localised action, nutritive, sedative, or stimulant, it is sought by methods of general electrisation not only to influence for good the functional activity of organs, but to exercise a demonstrable, perhaps even a measurable, influence on the whole process of nutrition. It is true that the physician still finds himself without any one great guiding principle of universal application whereon to base his electrical procedure. He has, so to speak, no compass to steer by. But, on the other hand, endless facts have been elicited of present usefulness and future promise. These facts, multiplied, collected, and arranged, must ultimately disclose some wide generalisation; in the meantime they are sufficient to guide him in his practice. If he has no compass to steer by he has at least *landmarks* to keep him in a safe course. Such landmarks are to be looked for in the physical character of electric currents, in their action on living structures as demonstrated by physiological experiment, and in a knowledge of their therapeutic action as derived from experience. A familiarity with one and all of these landmarks is of the first necessity, and the study of electricity in diagnosis and in treatment resolves itself into a study of these guiding landmarks. It is to a consideration of these that we must address ourselves and it is to a bird's-eye view of the first line of these landmarks—viz., the physical character of currents — that I should like chiefly to draw attention. Nothing is more false than to regard electricity as a simple agent, always the same in kind, acting in the same way, applied by the same method, and having identical results. In point of fact, its effect depends upon the kind of electricity used—i.e., the modality in which electricity is employed; in other words, on the physical character of the current. A continuous current has a very different action on the living organism from an alternating one, and alternating ones are radically different in their effects according to the form and period of the electro-motive force curve. Nor is it right to regard the action of electric currents on the living organism as immediately due to electric energy considered as something by itself—an imponderable and immaterial physiological agent. Electricity in all its varied modalities acts through the electrolytic or other material molecular changes which it brings about.

[The physical characters of the "three conventional currents ordinarily used in medicine"—the galvanic, the faradaic, and so-called static—were then briefly considered, but reserved for closer study. It was pointed out that these currents are beginning to be supplemented and to some extent supplanted by electricity in certain new modalities. The lecturer having explained the continuous and alternating dynamo currents, and demonstrated the power of the "static induced" current to bring about powerful and painless muscular contractions, "currents of great frequency and high potential" were considered at a greater length.]

Their alternations are to be counted by hundreds of thousands a second. For medical use they are generally obtained by means of the oscillating Leyden jar discharge traversing a solenoid. Such currents may carry energy enough to light a five-candle power lamp, and if the human body with its thousands of ohms resistance be at the same time placed in circuit there is scarcely a perceptible diminution in the brightness of the glow, and notwithstanding the tremendous amount of energy passing there is scarcely a consciousness of its passage.

[A five-candle power lamp was then incandesced by the current in question. The circuit was then broken and completed through the body, the latter being the only route open to the current; the lamp again glowed with scarcely any sensory or other effect on the part of the person through whose body the current passed. The importance of the fact that the body can stand so large an amount of energy in this form would presently appear.]

The physiological effects of such currents are according to d'Arsonval as follow: (1) an analgesia at the point of entry and exit of the current; (2) a fall of arterial tension; (3) increased action of the skin; (4) increase in the "respiratory combustions"; and (5) the virulence of blue pus is attenuated and after about half an hour's application the bacillus dies. More recently the same experimenter has addressed himself to "the soluble products of the microbes"—the toxines. Taking a U-shaped tube having a partition at its lowest part to prevent admixture of liquids he filled each branch with an active diphtheritic toxine and in each placed an electrode, one connected with the positive and one with the negative pole of this current. Now as the current which traverses the toxine is oscillating at the rate of at least 200,000 alternations a second it is possible to form some idea of the molecular shaking to which the culture is subjected. Having thus electrised an active diphtheritic toxine for fifteen minutes d'Arsonval and Charrin had injected 2·5 c.c. into three guinea-pigs and the same amount non-electrised into three other guinea-pigs. There was no doubt about the result. The "control" animals died within a few hours of each other in about twenty-four hours; the others were alive and well. The importance of the fact that the body can bear such high amounts of energy in this form is from a clinical point of view at once apparent. These currents being without action

Digitized by Google

n the sensory and motor apparatus of our bodies, may it not e possible to use such currents strong enough to attenuate he toxine in the living body?

ANALYSIS OF TWO HUNDRED CASES OF SCIATICA.

BY SAMUEL HYDE, M.D. ST. AND.

A LARGE proportion of the cases that present themselves or treatment at thermal stations consists of painful nerve ffections, and a great many of these are made up of lesions f the sciatic nerves and their branches. In consulting the iterature of sciatica I have been forcibly struck with the aucity of clinical information which has been recorded pon the subject. It was this consideration which led me a hort time ago to tabulate a number of cases of sciatica vhich have come under my personal observation at Buxton nd for this purpose I selected 200 cases occurring in ecent years. My analysis revealed to me some striking acts, which were not only at variance with my own precon- eived notions, but with those of many other observers. A rief record of my investigation may be of interest to some f my professional brethren, and I therefore submit the ollowing figures and remarks.

The 200 cases consisted of: Males, 112, or 56 per cent.; emales, 88, or 44 per cent.; right side affected, 72, or 36 er cent.; left side affected, 62, or 31 per cent.; both sides ffected, 66, or 33 per cent.; inflammatory, 109, or 54·5 per ent.; and non-inflammatory, 91, or 45·5 per cent. In 157 ases the patients were suffering from a first attack, in 22 from second, in 13 from a third, in 1 from a fourth, in 3 from a ixth, in 1 from an eleventh, in 2 from a twelfth, and in 1 rom a fourteenth. The attack had lasted under one month n 45 cases, from one to three months in 70, from three to ix months in 29, from six to twelve months in 29, from one o two years in 15, three years in 6, four years in 1, five ears in 2, and six, seven, and ten years respectively in each f 3 other cases. The ages were: Under fourteen years,); between fourteen and twenty, 1; between twenty-one nd thirty, 26; between thirty-one and forty, 36; between orty-one and fifty, 47; between fifty-one and sixty, 53; etween sixty and seventy, 34; and between seventy nd eighty years of age, 3 cases. As exciting or redisposing causes the following were ascertained as robable: Gout, 48, or 24 per cent.; debility, 43, or 1·5 per cent.; rheumatism, 35, or 17·5 per cent.; chill r exposure, 26, or 13 per cent.; influenza, 12, or 6 per cent.; lcohol, 9, or 4·5 per cent.; constipation, 8, or 4 per cent.; næmia, 7, or 3·5 per cent.; malarial, 7, or 3·5 per cent.; nd injury, 5, or 2·5 per cent. The duration of the treat- nent at Buxton lasted from three days to twelve weeks, or n average of two and a half weeks. The results of treat- nent were as follows: Cured, 90 cases, or 45 per cent.; im- roved, 101 cases, or 50·5 per cent.; and no better, 9 cases, r 4·5 per cent.

Remarks.—In his excellent little treatise on Sciatica Dr. Symons Eccles states that of the sixty-five cases observed y him forty-one occurred in females. I confess to some urprise when I read this statement, which is opposed to such uthorities as Dr. Gowers, the late Professor James Ross, and thers, who hold that the disease is more frequent in males han females. An examination of these 200 cases confirms he opinion of these authorities, 56 per cent. consisting of nales, as compared with 44 per cent. of females. An in- eresting point revealed, perhaps for the first time, by he above figures is that unilateral attacks, bilateral ttacks, and double attacks occur in almost equal pro- ortions. This is the more interesting, I think, when onsidered in its relation to the more common causes of ffection, as I shall note later. Furthermore, of these 00 cases those showing inflammatory signs were 9 per cent. n excess of those which appeared to be of a purely neuralgic orm. It would seem that the liability to recurrent attacks s not great. Only 22 of the cases were suffering from a econd attack, 13 from a third, 3 from a sixth, 2 from a welfth, and 1 from a fourteenth. As to the duration of he attacks, the largest number, 70, had lasted from one to hree months, but 27 had been suffering over a year and 1 s long as ten years. None of these cases were under fourteen years of age and only one between the ages of fourteen and twenty. The majority, 137, occurred after forty years of age and most of these—viz., 26 per cent.—were between the ages of fifty and sixty. My experience thus differs from the late Professor James Ross, who found the largest number between forty and fifty years of age.

The most common cause of sciatica has been hitherto generally ascribed to exposure to cold, but it is remarkable that in only a small proportion—13 per cent.—of these cases could I obtain any distinct trace of such an exciting cause. In the majority—comprising 87 per cent.—there was no such history, and the large proportion of 63 per cent. were traceable to some constitutional condition, such as gout, rheumatism, and general debility. Nor does my experience support the theory that constipation is a very fruitful cause of sciatica, only 4 per cent. of these cases being fairly attributable to that as an exciting cause. I am, of course, quite prepared to admit that these figures would be subject to considerable modification in some respects were a like number of cases selected from hospital practice, but I think they may be taken to represent fairly the cases met with in ordinary private practice. I also think that the foregoing facts afford sufficient ground for questioning the assumption, which has until now been accepted by most of those who have written upon the subject, that sciatica is in the majority of instances due to some local cause, such as exposure to cold or to pressure from constipation. Apart from the fact that of my 200 cases in no less than 63 per cent. there was no history of chill or constipation, but distinct signs of gout, rheumatism, or debility, I think the fact that the right, left, and both sides were pretty equally affected is additional evidence in favour of some general, rather than local, condition operating as the most common cause of sciatica. For example, if constipation were such a common cause as hitherto believed, then one would expect to find left sciatica much more frequent than right, on account of the position of the rectum, but this is not the case. Likewise, if exposure to chill were the frequent cause that it has been held to be, then one would expect to see more cases in which the pain or numbness would be confined to the limited area of exposure and not so many cases as one actually does see of diffused and distant symptoms. I have not space in this article to dwell upon the details of the treatment which I used in these 200 cases. Suffice it to say that the main factors in the treatment were change of air, the Buxton thermal waters, internally and externally, including warm douches, dry and wet massage, generous diet, gentle open-air exercise, and drug-tonics. The results of this treatment of sciatica have in my experience been amongst the most gratifying in this particular branch of practice. As already stated, out of the 200 cases selected indiscriminately, 90, or 45 per cent., were cured before they left Buxton; 101, or 50·5 per cent., were improved; and only 9, or 4·5 per cent., left the Spa no better. A large proportion of those who were only improved when they left were reported afterwards to have gradually but completely recovered. The duration of the treatment varied from three days to twelve weeks. These are results which it will, I think, be admitted are very remarkable, and should encourage physicians to make use of the remedial influences presented by the dry, bracing mountain climate and the baths and waters of Buxton and similar spas when other remedies fail to give relief in this painful disease.

Buxton, Derbyshire.

DISPLACEMENT OF THE LIVER.

BY J. SNOWMAN, M.R.C.S. ENG., L.R.C.P. LOND.

OF late increasing attention has been drawn to the various pathological features which collectively constitute the condition now generally recognised as enteroptosis. Till quite recently the only organ known to exhibit this phenomenon was the kidney, the floating or movable kidney having for some time acquired a permanent position in surgical nosology. It has now been ascertained that the conditions which produce this unstable state of the kidney are not confined to that organ, but that they act with similar effects on the liver; indeed, it appears from a recent article by Mr. Treves[1]

[1] Brit. Med. Jour., Jan. 4th, 1896.

Digitized by Google

that the stomach, spleen, and transverse colon may be displaced in a similar manner. His paper on the subject contains the first clear account of movable liver published in the United Kingdom. A reference to the condition occurs in the new edition of "Quain's Dictionary of Medicine," where it is stated that "notwithstanding the absence of any post-mortem examination a liver, normal in form and volume, may under certain conditions of very rare occurrence be capable of considerable displacement within the abdominal cavity" (W. Johnson Smith). The condition is probably not so rare as this remark suggests. In the June number of the *Canadian Practitioner* for 1895 there is given a list of eighty cases collected from various sources. In 1878 twenty cases were collected by Wickham Legg, who threw doubt on the accuracy of the diagnosis. In 1885 a monograph appeared by Landau of Berlin on Movable Liver and Pendulous Abdomen in Women. In the recently published work by Osler on Abdominal Tumours a very succinct account of a case is given. The latest investigations on the subject have been made by Faure, who has supplemented his researches by experiments on the cadaver. No doubt when the fact of the existence of this condition becomes more widely known and the proper method of examination is adopted numerous examples will be forthcoming.

A very typical case has come under my notice in the person of a married woman aged sixty-four years whom I first saw on Dec. 16th, 1894. She had been ill for a week with loss of appetite when jaundice set in, with constipation, clayey stools, and bilious urine. The prominent feature on examination was that hepatic dulness extended to just below the level of the umbilicus; the organ easily admitted of palpation through the thin abdominal walls, and its lower edge was extremely well defined. The heart and lungs were normal. This great hepatic enlargement seemed to negative the diagnosis of catarrhal jaundice, and it apparently belonged to that group of cases described by Bristowe as "hypertrophic cirrhosis of the liver." Other causes of hepatic enlargement, as cancer, syphilis, abscess, &c., were easily excluded. Against the diagnosis of hypertrophic cirrhosis were the facts of the somewhat sudden onset and the absence of an alcoholic history. The progress of the case proved that it was ordinary catarrh of the bile-ducts, and though at first refractory to treatment by the middle of January, 1895, the patient was in perfect health. More detailed examination of the liver during the illness revealed the following facts. The liver dulness did not begin till the costal margin (this was originally thought to be due to pulmonary emphysema). The whole mass of the liver could be easily moved through the lax abdominal walls, and when the patient arose to the erect posture the whole organ actually dropped two or three inches and could be felt in the inguinal region. The upper edge could not, however, be felt beneath the ribs. This condition of the liver remained *in statu quo* after the patient's recovery, showing that she had suffered from an attack of catarrhal jaundice in a movable liver. The patient had evidently long been the subject of this condition without it affecting her general health in any particular, and it undoubtedly would never have been detected had not the jaundice directed special attention to her liver. Repeated examination failed to reveal any ptosis in the spleen or kidneys, and the patient being a thin, spare woman with lax abdominal walls examination presented no difficulty.

The comparatively few cases on record render it difficult to generalise on the subject. Many of the cases have been associated with obvious disease sufficient to account for the displacement of the liver, such as spinal curvature, tumours within the thorax, and adhesions contracted as a result of inflammatory disease within the abdomen. These cases should be excluded from the category of movable livers, which depend for their production mainly on a relaxation of the suspensory ligament. Anatomically the liver should be more easily susceptible of displacement than the kidney; the latter is fixed in position by a mass of fatty tissue, while the former is merely slung up against the roof of the abdominal cavity. A displacement of the kidney almost necessarily involves tension on vessels and nerves which may be absent in a similar condition of the liver, and this would account for the existence of symptoms in the case of movable kidney and their comparative absence in that of movable liver. We are, however, confronted occasionally with symptoms of vomiting and epigastric pain in cases of movable liver. These symptoms may be of sudden onset, while a sensation of weight and dragging often forms a constant complaint. The relaxation of the suspensory ligaments of the liver must be referred to that undefined idiosyncrasy of tissue recognised in fibrous structures which consists of a loss of tone, stretching, and elongation. We know nothing scientifically about this peculiar "habit" of tissue, except that it generally exists in thin, spare subjects, mostly women who have borne numerous children. The custom of tight-lacing, as it displaces the liver, may be a factor in rendering it movable. Prolapsus uteri has frequently been noted in association with movable liver. It only remains to add that where this condition gives rise to no symptoms no interference is called for. When it has caused discomfort in the abdomen complete rest in bed has been followed by satisfactory results. Abdominal supports have been invented for some cases where this condition has produced great distress, and in a few severe cases associated with intense neurasthenic symptoms the liver has been stitched to the abdominal parietes.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SWELLING OF THE PAROTID GLAND.

BY W. T. COCKING, M.D. LOND.,
PHYSICIAN TO THE SHEFFIELD GENERAL INFIRMARY.

THE following brief notes may be of interest in connexion with Mr. Raymond Johnson's very instructive paper on Some Unusual Cases of Swelling of the Parotid Gland.[1]

In 1894 a man aged forty years, who was under treatment for dyspepsia and constipation and certain functional nervous symptoms, complained that for the last two or three years he had been much troubled with a swelling in the region of the right parotid which came on suddenly whilst eating and lasted for an hour or two. The swelling was somewhat painful and interfered considerably with mastication. He had found that pressure with the hand caused a profuse discharge of fluid into the mouth, after which the swelling gradually lessened and disappeared. The fluid had occasionally a nauseous flavour. The left gland was also affected, but much less frequently than the right. On one occasion only was an opportunity afforded of a personal examination of the swelling, which, however, had then to a great extent subsided. At that time some fulness and slight redness of the skin were detected below the right ear, and on firm pressure a copious jet of clear watery fluid was observed to escape from Stensen's duct. Nothing abnormal was at any time discovered in the mouth. Change of air and improvement in the general health resulted in the complete disappearance of the affection for some months. At the present time the attacks are considerably less frequent and give rise to much less discomfort than formerly.

Sheffield.

ON THE INEFFICACY AGAINST EARLY SYPHILIS OF IODIDE OF POTASSIUM WHEN ADMINISTERED ALONE.

BY WALTER G. SPENCER, F.R.C.S. ENG.,
SURGEON TO THE OUT-PATIENTS AND THROAT DEPARTMENT OF WESTMINSTER HOSPITAL, ETC.

SOON after the introduction of iodide of potassium and as a reaction from the excessive use of mercury it was frequently given alone, but it must be now very rare to find both medical man and patient trusting entirely to this drug. Lest anyone should be tempted to try the experiment I may record the following results, since the account given of himself by the man appears to me to be trustworthy.

The patient, a man aged thirty-one, acquired a hard sore some three years ago, which was followed by enlargement of the inguinal glands, slight pains in the limbs, and five months after the primary sore by an ulcer on the tongue. He-

[1] THE LANCET, April 18th, 1896.

Digitized by Google

was ordered by a medical practitioner to take ten grains of iodide of potassium three times a day, and he continued to do so for two years after the ulcer had healed. He took the medicine regularly, he never took anything else, and he never exposed himself to fresh infection. Since the ulcer healed he has not felt anything wrong with himself. Three months after leaving off the iodide, believing from what the medical man said that he was cured, he married. After three months his wife aborted. On her recovery the husband brought his wife to me. She had a characteristically dusky, scaly rash on the arm and legs, with nocturnal pains in the bones. Both husband and wife were treated with mercury, and the wife took it regularly throughout the second pregnancy, which soon began. She has now a baby one month old, whom I have seen and who appears to be perfectly healthy.

"RUPTURE OF THE TERMINAL EXPANSION OF THE EXTENSOR COMMUNIS DIGITORUM."

BY T. N. THOMAS, L.R.C.P. LOND., M.R.C.S. ENG.

THE clinical notes which have lately appeared in THE LANCET under the above heading[1] induce me to report the following case which is now under my observation. It differs from the others in the fact that the dislocation was compound, and the way in which it was produced is certainly peculiar and worthy of record.

A man aged twenty-five years was indulging in a game of Rugby football on Feb. 15th last, and while playing as forward was following up a long kick when one of the opposing three-quarter backs took the ball and was attempting to run round him on his left-hand side when the forward made a grab at his opponent's jersey—a thick worsted one—with his left hand, but only succeeded in engaging the end of his middle finger in the collar, and as soon as his weight told on the finger it seemed to slip and when he looked at it a moment later it was bent at a right angle and the head of the bone was protruding through the skin at the back of the last joint. He straightened the finger and left the field. When I saw him an hour later I found the skin over the back of the last joint of the left middle finger and the posterior ligament, or, rather, what represents the ligament in that situation—namely, the terminal expansion of the extensor communis digitorum tendon—completely torn across, and when he flexed the joint the head of the second phalanx protruded through the wound. After washing thoroughly and dressing antiseptically the finger was placed on a straight splint, upon which it was kept for five weeks. At the end of that time the wound was quite healed under a scab, which came off a week later. Upon removing the splint the patient was unable to straighten the terminal phalanx voluntarily beyond an angle of about 135°, and though in the joint itself the movements of flexion and extension are quite free he has not yet—ten weeks after the accident—regained the power of extending it beyond that angle. The patient, whose work consists for the most part in corresponding, was not incapacitated by the accident from following his occupation for a single day. I am much encouraged by the report of Dr. Kidd's case, in which complete recovery took place after an interval of eight months, and have given my patient instructions to persevere, and I believe he very patiently and intelligently carries out my wishes.

Leicester.

"CEREBRAL MENINGITIS FOLLOWING INFLUENZA."

BY WILFRED R. KINGDON, M.B. DURH.,
LATE RESIDENT MEDICAL OFFICER AT THE STOKE NEWINGTON DISPENSARY, LONDON.

I RECENTLY attended a case which presents some likeness to one recorded in the pages of THE LANCET[2] some time ago.

I first saw the patient, a boy fourteen and a half years of age, on a Sunday, when he presented the following symptoms: severe frontal headache, excessive lacrymation together with pain on pressing over the eyeballs, aching pains in the lumbar region and legs, furred tongue, anorexia, somewhat scanty and high-coloured urine, constipation, a temperature of 104·2° F., and a pulse of 117. From what the boy's mother told me I came to the conclusion that the illness had commenced with a rigor and some sickness, but apparently no actual vomiting. There seemed to be no doubt whatever but that the boy was suffering from influenza, and I ordered him seven grains of phenacetin powder to be taken at once and a mixture containing quiniæ sulphas and liquor ammoniæ acetatis. The next day I found the patient in a much more comfortable condition; the temperature was 100·8° and the pulse 100. The pains were better, the tongue was slightly less furred, and he could be induced to take a little milk pudding. This improved condition continued for a week, but his temperature never fell below 100°. At the end of this period he began to lack interest in things which were going on about him; he had a dull, almost stupid expression; he did not seem to understand what was said to him, and at times he talked incoherently and picked at the bedclothes. The ophthalmoscope revealed optic neuritis; there was intolerance of light, the head was slightly retracted, and the *tache cérébrale* could be demonstrated, but the abdomen was not boat-shaped. The preponderance of evidence certainly pointed to cerebral meningitis. This condition of affairs had been going on for just three days when I was called in great haste to see the boy, "as he was in a fit." On arrival I found the patient seized with tonic contractions of nearly every muscle of the body; there was opisthotonos, and both sides of the body seemed about equally affected. He soon relapsed into a comatose condition and died in about ten and a half hours after the onset of the spasmodic contractions, notwithstanding the fact that he had constant care, frequent liquid nourishment, and stimulants, to say nothing of numerous drugs. Potassii bromidum, quiniæ sulphas, liquor ammoniæ acetatis, phenacetin, sodium salicylate, and other things were alike of no avail. No necropsy could be obtained, but there seemed to be no doubt that it had been a case of cerebral meningitis.

Now, how was this meningitis caused? A careful examination revealed no condition likely to give rise to the disease, and the question seems to be: Is meningitis to be put down as one of the sequelæ of influenza? I cannot give any reason why the one disease should lay the foundation of the other, neither is it my wish to advance any theory. It may be that this was but a coincidence and that lowered vitality was the predisposing cause alike of both; however, I have given only the simple facts, and it is thus open to each and every reader to take his own view of the case.

Queen's-crescent, N.W.

[2] THE LANCET, Feb. 22nd, 1896.

THE PORTSMOUTH WATERWORKS.—The proposal of the Portmouth Corporation to purchase the enormous undertaking of the water company was advanced a distinct step at a special meeting on April 28th. A special committee had had several interviews with the directors of the company, and the present scheme stands as follows: It is estimated that a total amount of consolidated stock will be required to the extent of £1,040,000. The shareholders will receive £915,000 in stock as representing the full dividend of £27,448; £104,500 will be absorbed in the payment of loan capital; £3550, seven years annuity for the secretary; £5880 for seven years directors' fees; and £4113 for unpaid back dividends. The estimated legal costs of the necessary Bill in Parliament are £6000, or a total, as above stated of nearly £1,040,000. Two and a half years ago, when the purchase negotiations fell through, the nett increase of the company's revenue was put at £600 a year; now it is over £1000, and so the directors ask more money for their concern. The gross revenue of the company is £53,000 a year and grows, of course, with the town, whose rateable value last year increased by £12,000. It is calculated that with ninety years' redemption of the stock the corporation would gain by the transaction in the form of a small actual yearly profit; at eighty or eighty-five years' redemption there might probably be a small deficit to recoup from the rates. There was some hesitation apparent in the speeches at the council meeting, but as the committee's report was carried by thirty-one votes to two it seems likely that the corporation, remembering the mistake of two years ago, will not allow it to recur for the sake even of a thousand or two paid on what they may consider heavy claims.

LONDON HOSPITAL.

THREE CASES OF FOREIGN BODIES IN THE ALIMENTARY CANAL; REMARKS.

(Under the care of Mr. C. MANSELL MOULLIN.)

THESE cases form an interesting contribution to our clinical records of foreign bodies in the alimentary canal. Case 1 is noteworthy from the fact that such a sharp-pointed body as a broken bonnet pin had passed safely so far along the intestine as to reach the neighbourhood of the ileo-cæcal valve. Its removal in the way described after abdominal section was clearly the safest procedure for the patient, for the dangers of perforation of bowel by the sharp end of the pin beyond the point reached were considerable. Case 2 is important inasmuch as it draws attention to the difficulty sometimes experienced in detecting the presence of a flattened object in the œsophagus, a difficulty which we have also seen in hospital practice in a similar case—the impaction of a tooth-plate. It also shows the great danger which the prolonged retention of a foreign body in the œsophagus gives rise to from the liability of the ulceration caused by its presence to extend through the wall and cause injury to the important structures adjacent, whether artery, bronchus, nerve trunks, or pericardium. Case 3 is an example of a method of treatment very useful in cases of round, smooth bodies of a size not very disproportionate to that of the œsophagus.

CASE 1.—A well-grown girl nineteen years of age was admitted to hospital on Dec. 14th, 1895, with the statement that she had swallowed the greater portion of a hat-pin. According to the account that she gave of herself she had felt something tickling at the back of her palate and had taken one of her hat-pins and had passed it into her mouth head first to rub it against the mucous membrane. The shaft of the pin broke and the head end of it dropped into her throat and was immediately swallowed. She brought the broken end, and by comparison with another the portion she had swallowed was nearly four and a half inches in length with a bead on the end about the size of a small Barcelona nut. She went at once to a druggist who gave her an emetic, making her violently sick, but fortunately without doing her any harm. The patient complained of great tenderness and of a sharp stabbing pain in two places, one in the front of the chest an inch and a half from the middle line and a short distance above the nipple, the other behind a little to the left of the third dorsal vertebra. As it was thought that during the vomiting caused by the emetic there was a possibility of the pin, which went down head first, being driven upwards into the wall of the œsophagus, a probang with a metal end was passed down into the stomach, but nothing was felt. The patient was very hysterical, so much so that her sister, who came to see her, refused to believe that she had swallowed anything at all; but as the account that she gave of herself did not vary, and the pain and tenderness continued and were made worse by attempts at swallowing, an exploratory operation was advised and performed on the fourth day after admission. An incision two inches long was made in the middle line above the umbilicus and the stomach drawn into the wound and carefully examined without result. The finger was then passed down into the right iliac fossa and the head of the pin felt at once in a portion of the small intestine immediately above the ileo-cæcal valve. The wound was slightly enlarged in a downward direction to allow the intestine, which was nearly fixed, to be brought to the surface. Two Lembert's sutures were passed, one on each side of the head, an incision made between them, and the pin extracted. The sutures were then tied, a third passed over them, and the intestine dropped back. The abdominal wound was then closed in the usual way. For some days the patient was exceedingly hysterical and suffered from various complaints, but recovery was uninterrupted from the first. The pain in the chest continued off and on until she was well.

CASE 2.—A man thirty-one years of age was admitted to hospital on Jan. 11th, 1894, with a history that the day before he had swallowed a plate with six false teeth attached to it. He had gone to bed without removing it and woke up with a fit of coughing. Suddenly he felt the plate slip and pass down his throat, giving him the sensation that he was choking. There was no hæmoptysis or hæmatemesis, but on coughing or swallowing anything solid he complained of a certain amount of soreness felt behind the middle of the sternum. There was no difficulty in swallowing, nor did the food seem to stick anywhere. A probang was passed on several occasions, and twice, as it was being withdrawn, when the point was eleven inches from the teeth, a faint rub was felt, as if it touched something hard. Nothing could be heard or felt when the probang was being pushed down, and although many attempts were made the foreign body was not felt (if, indeed, it was the foreign body that caused the sensation of rubbing, for of this there was some doubt) more than twice. Nothing was passed per anum. The patient felt perfectly comfortable and could swallow anything, so that at the end of a fortnight he was discharged. A twelvemonth later I heard accidentally that in a row in a public-house he was suddenly seized with such furious hæmoptysis that he died on the spot. The plate had ulcerated through the wall of the œsophagus into the aorta by the side of the left bronchus.

CASE 3.—A baby six months old was admitted to hospital in June, 1893, with the history that about six hours before the patient had swallowed the clamp of a feeding-bottle. The clamp was of metal in the shape of a cylinder half an inch long and three-eighths of an inch in diameter, with a screw projecting from its upper end. It had been felt in the child's mouth and had been driven lower and lower down by successive attempts at removal, until, at the time of admission, it had descended to the level of the top of the sternum. Its shape and the very small amount of space available rendered it impossible to extract it from above. The prospect of success if an attempt was made to remove it through an external incision was very remote, so it was decided that the best thing to do, as it had already travelled so far, was to endeavour to push it on. This was done with a gum elastic catheter, very slowly and gently, until at length it suddenly slipped into the stomach. The child suffered no further inconvenience and the cylinder was passed per anum two days later.

Remarks by Mr. MANSELL MOULLIN.—These three cases of foreign bodies in the alimentary canal are of somewhat unusual character. It is possible that the bonnet pin, which in the course of five days had already reached the ileo-cæcal valve, might have been passed naturally; but it is at least doubtful whether, with its length of over four inches, it would have succeeded in steering successfully round the fixed corner at the valve without catching. The pain and tenderness, which were so definite and so constant as to be considered to justify exploration when taken in conjunction with the history of the emetic, were in all probability subjective, as they continued off and on until the patient's health was restored, or there may have been some slight injury to act as a foundation for them. In the second case it is difficult to understand how a plate of such a size, carrying six teeth, could have succeeded in concealing itself so thoroughly. Probably its convex border fitted into a recess above the left bronchus, where there is sometimes a little dilatation of the œsophagus, and its concave one became coated over with mucus. It was only touched twice by the probang as the instrument was being withdrawn, never while it was descending, and the patient very soon lost all consciousness of anything being there, even when he swallowed solids.

SUSSEX COUNTY HOSPITAL.

A CASE OF SUTURE OF PERFORATED TYPHOID ULCER; NECROPSY.

(Under the care of Dr. HOLLIS.)

THERE have not been many cases of operation for perforation of typhoid ulcer in this country, and we need all the

Digitized by Google

ecords of cases submitted to operation, in order that some eneral rules may be agreed upon, and that the necessity for urgical help in such cases may be impressed on those in harge. Dr. Van Hook after a careful consideration of the ques- ion of perforation occurring in the course of typhoid fever ame to the following conclusions amongst others: (1) there s no rational treatment for perforation in the course of yphoid fever except laparotomy; (2) when perforation occurs n typhoid fever the indication for operation is imperative; 3) the only contra-indication is a moribund condition of the atient; (4) collapse is often, at least temporarily, relievable y hot peritoneal flushing; (5) the stage of the fever is not o be considered as an indication or as a contra-indication or laparotomy; (6) the severity of the typhoid fever is alone ot a contra-indication; (7) early laparotomy offers the ost hope; (8) the symptoms of peritonitis should not be waited before operating; and (9) the published statistics f laparotomy for this condition are strongly in favour f operation, &c. It is difficult to give a very favour- ble prognosis in any case of perforation of intestinal lcer, and although the operation for closing it may ave been done quickly and with the utmost skill there s in these cases of typhoidal perforation a greater tendency o recurring collapse and the many dangers of the remaining eriod of the fever have to be encountered and overcome. As the perforations in typhoid fever are nearly always in the ower part of the ileum a prolonged search is not usually ecessary, the opening is generally small, and although the all of the bowel is softened and friable, the insertion of utures may be effected without much difficulty. It is dvisable to close the opening at once and cleanse the eritoneum very carefully rather than make an artificial nus, although it is conceivable that in some instances uch a proceeding might be the better one to adopt. There is a doubt if some of the cases published as such were really of the nature of those under considera- tion. For the notes of the case we are indebted to Dr. A. Stanley.

A man aged thirty-three years was admitted to hospital on March 6th, 1896, under the care of Dr. Hollis, with all the physical signs of typhoid fever—the enlarged spleen, the exanthem, diarrhœa, a continuously high temperature, bronchitis, and some distension of the abdomen. He had had headache and lassitude for eleven days before admission, but did not take to his bed until three days before admission. On the 10th there was hæmorrhage from the bowel. On the 12th perforation was indicated by increase of abdominal distension, absence of liver dulness and of abdominal respiratory movements, by pain, rigidity, and vomiting. He was seen by Dr. Hollis and Mr. Furner in consultation and an immediate abdominal section was resolved upon. The abdomen was opened in the middle line and the peritoneal cavity was found to contain gas, blood, and fæcal matter. The perforation was found eight inches from the ileo-cæcal valve, the ragged edge well inverted and Lembert's sutures were applied. The peritoneal cavity was washed out and the wound closed. The patient was very collapsed after the operation. He did not sleep the same night, and next morn- ing the pulse was extremely feeble and running. There was some tympanites which was relieved by passing the rectal tube. Later he began to vomit altered blood, but after the stomach had been washed out with hot water this ceased. The pulse became still weaker. Three pints of normal saline solution were infused into the median basilic vein. He gradually became exhausted and died thirty-six hours after the operation.

Necropsy.—The peritoneal cavity was found remarkably clean, the coils of gut being covered here and there with thin lymph and the recto-vesical pouch containing a few ounces of blood-stained fluid. There had been no second perforation. The gut in the neighbourhood of the sutured ulcer was deeply congested. The sutures held well and the reparative process appeared to be taking place in a healthy manner, but at the lower end of the row of sutures the typhoid necrosis had just spread through to the peritoneal surface of the ileum; but there was no perforation. The interior of the ileum showed several Peyer's patches in a state of typhoid hyperplasia—thickening, but no tendency to sloughing or separation of sloughs except at the situation of the sutured perforation. Here the necrosed mucous membrane was well turned in so that fairly healthy peritoneal surfaces were apposed by the sutures, except at the lower part where there was some necrosis.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Malarial Hæmatozoon in Ashanti Fever.—Healing of Incisions in Vegetable Tissues.—Pneumonomycosis.—Exhibition of Specimens.

A MEETING of this society was held on May 5th, Mr. BUTLIN, President, being in the chair.

Dr. NORMAN MOORE read a paper on Malarial Hæmatozoon in Ashanti Fever. He pointed out that the hæmatozoon which resembled hæmamœba præcox occupied a red blood corpuscle. It was ovoid with a curved axis and contained in the middle some pigment granules. From its greater curve projected two small processes. In this circumstance it differed from any of Laveran's figures as well as from those of Marchiafava and Bignami. Projections from the surface of the corpuscle were shown in one of Laveran's figures, but they were the pointed ends of the crescent-shaped organism. The projections in this specimen did not appear to be flagellæ, but rather resembled the pseudo-podia of some protozoon. The blood was taken from the finger of the patient after proper clean- ing and the specimen was at once exposed to osmic acid. The hæmatozoa were not numerous. The blood corpuscle generally seemed natural. A specimen examined two days before this showed only a very few spherical bodies with pigment. The patient was an officer who served in the recent expedition. He felt quite well on the way up to Kumasi, but on the way back was conscious of a slight degree of weakness and fever. After embarkation he rapidly became ill and at Las Palmas on the voyage home had a daily temperature of 104° F. and a continued fever. This diminished before his arrival at Plymouth and he was able to do duty on landing in the Thames. A week later he was obliged to go to bed, and from March 8th to 19th suffered from daily fever with an intermission of about four hours, accompanied by well-marked enlargement of the spleen and liver, much vomiting, and inability to take food. His other organs seemed normal. Some years before he had had acute endocarditis and had a febrile attack which did not recur and was probably not malarial at Wady Halfa. His highest temperature each day was about 102·5°, but sometimes reached 104°; the fever ceased on March 20th and he had no relapse. The specimen was taken about three hours before the usual hour of highest temperature, and up to that time he had had no quinine for a fortnight. Dr. Moore thought it was worth while to note the peculiarity of form in the hæmatozoon, even if it were but a circumstance in its phases of development and not a character indicating species.—Dr. MANSON asked if the specimen under the microscope was the only one with the peculiar projections and whether these projections stained with eosin or methylene blue. If the former he opined that the fact afforded evidence of their being part of the container and not the parasite itself. He had examined several specimens of blood from similar cases, and in all the crescentic form of the parasite was present.—Dr. MOORE, in reply, said that under a higher power it would have been easy to see that the projections were not stained by eosin but by the methylene blue. They were consequently part of the parasite and not an altered blood corpuscle. They had seen very few hæmatozoa and none as well marked as the one on view.—Mr. HUSSEY said they had found one other crescent, which he thought showed sufficiently distinct projections from the convex edge to make it seem probable, at any rate, that it was not due to pressure on the film during preparation. He himself had never seen anything like it before. He considered that there was no doubt that the projections stained with the methylene blue and not with eosin.

Mr. S. G. SHATTOCK read a communication on the Healing of Incisions in Vegetable Tissues, giving a detailed account of the different methods as studied experimentally by him- self. The methods were comparable to those of first inten- tion and third intention in the human subject. He com- menced by adverting to the process of "immediate union," which assumed the reunion of the parts of cells actually divided. He had never observed this in plants in spite of every care, and he did not believe that it occurred in animal tissues, even in the case of such a cell as a leucocyte, for Hofer had shown that if an amœba be divided two indi- viduals resulted, of which the one wanting the nucleus after

Digitized by Google

a while perished. Under healing of incisions in vegetable tissues by first intention Mr. Shattock stated that in general it consisted in cell division on either side of the face or plane of the injury, the remains of the cells laid open in the course of the incision became compressed, and as growth proceeded the line of these compressed remnants was interrupted or broken into segments by the interpolation of new cells. This was the most perfect process, occurring without any separation of the surfaces. Starch shed into the incision from the opened cells remained unchanged, doubtless because it was no longer within the sphere of living protoplasmic action; and its fate contrasted with that in slowly-dying branches, from which it was removed for consumption elsewhere, as happened in the life of ordinary foliage leaves. Sometimes the faces of the incision were separated by tension; the gap was then filled up by the growth of large callus cells from those bounding it. These callus cells might undergo secondary thickening, but no cork tissue was produced if the wound was sealed from the air, and it was upon this distinction that Mr. Shattock made the division into healing by first and healing by third intention. In the petiolus of Rheum rhaponticum a coagulable latex was shed into and filled the wound, and it hindered union just as blood-clot does in animal textures. Under third intention was considered the case where two surfaces were freely exposed and subsequently coalesced. Each of the surfaces under such circumstances became healed by the formation of a stratified layer of cork; but when they at length met, seeing that no further physiological reason existed for a protective production of cork, the latter was broken through by the subjacent parenchyma, which thus became continuous. This process occurred as the final stage in the well-known method by which denuded wood was covered over by callus in exogenous shrubs and trees, and it was commonly seen in grafting when no union took place between the cut surfaces, but between the callus from the cambium of the stock and scion. The analogy with the human process, however, differed in this, that the two surfaces were first healed by cork, whilst in animal tissues they remained granulating till brought together.

Dr. ARKLE read notes of a case of Pneumonomycosis in a young man twenty-two years of age. He had always lived a very healthy life and had never been ill. He was suddenly seized with gradually increasing dyspnœa and developed signs of very acute emphysema. Severe attacks of dyspnœa recurred from time to time and he became and remained markedly cyanosed. He continued in this condition for about four months, when he died in one of these attacks. Post mortem, on removal of the sternum both lungs bulged up through the opening and the heart was almost covered. Both lungs had large emphysematous bullæ upon them. The pleura was not adherent over the left lung, but on the right side there were loose but firm adhesions. On separating these and passing the hand to the posterior part of the thorax a gush of air escaped and the lung collapsed. Both lungs were enormously enlarged and over the back of the left lung the pleura was thickened and opaque. On section the lung tissue appeared more fleshy and coarser than normal. Under the microscope there were indications of universal emphysema. There was no sign of decomposition or mould in the preserving fluid, and sections of the lung stained with logwood showed the lung to be greatly disorganised in places with microscopical cavities and breaking down of the substance of the organ. The walls of the alveoli were notably thickened, as were also the smaller bronchi. The parenchyma contained a good deal of pigment. Permeating the lung could be seen an extensive mycelial growth, very recognisable, although there was no evidence of fructification. The hyphæ were for the most part delicate network, and were jointed and branched, with well-marked varicosities in places. The mycelial growths lay mostly in small cavities, which they might have made for themselves. They appeared to be the aspergillus.—The PRESIDENT mentioned that a somewhat similar case had been brought before the society many years ago, though not under this name. He asked whether there was much expectoration and whether the sputum had been examined microscopically. He asked, further, whether the emphysema occupied the usual situation or was more marked in other parts of the lung.—Mr. SHATTOCK observed that the principal point to be cleared up was whether the mycelial growth was ante or post mortem. He recalled the fact that fungi had been known to grow in Müller's fluid, so that it was necessary to exclude that possible source of fallacy. He mentioned that Dr. Bristowe had first described the aspergillus growing in a healing cavity in the lung, but long before that Hunter had described it as growing in the crops of birds.—Dr. ROLLESTON recalled that Dr. Delépine had described what he called aspergillus niger taken from an ulcer of the leg in a patient at St. George's Hospital. He had cultivated it and his results had been brought before the society in 1890 or 1891. He added that the growth evidently irritated the bronchi either directly or by some secretion.—Dr. PARKES WEBER asked whether it was supposed that the fungus grew into the tissues during life or that this had taken place during the interval following their removal from the body before the lungs were placed in a preservative fluid.—Dr. ARKLE, in reply, said that there was not much expectoration and unfortunately the sputum was not examined microscopically. The emphysema occupied the lungs throughout, but was most marked in the usual situations—i.e., the anterior borders and the apices. He himself felt convinced that the growth took place during life. He admitted that he had seen fungi growing in Müller's fluid, but only after the lapse of years, never in such fluid as one would be likely to use. Moreover, the specimens gave evidences of vital reaction which he thought showed that the growth was during life. There were plenty of ways in which the patient might have inhaled the spores, and very possibly it had begun as a case of bronchomycosis becoming pneumonomycosis later.—Dr. PARKES WEBER added that if the sputum had been examined no doubt mycelium would have been found therein. It was, however, in all probability in the air-passages and not in their walls that it first grew, and its presence there would determine irritation and consequently reactive phenomena, so that this was not *per se* evidence of ante-mortem growth in the walls or parenchyma.

The following card specimens were exhibited:—

Mr. SYDNEY JONES: Bony Tumour of the Scalp.

Mr. J. R. LUNN: Aneurysm of the Inferior Thyroid Artery.

Dr. H. C. SHARP (Truro): Primary Colloid Carcinoma of the Bladder.

Mr. ST. CLAIR THOMSON: Angeioma of the Septum Nasi.

Mr. TARGETT: (1) Psammoma of the Dura Mater; and (2) Colloid Duct Cancer and a Sarcoma in the Same Breast.

Dr. ROLLESTON: (1) Myeloid Cells in a Mammary Sarcoma; and (2) Loose Body Encysted in the Surface of the Liver.

Dr. OGLE: (1) Aneurysm of the Heart; and (2) Embolism of the Coronary Artery.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Articular Gout and its Treatment by Natural Sulphur Waters.

AN ordinary meeting of this society was held on April 15th, the President, Dr. HENRY LEWIS (Folkestone), being in the chair.

Dr. R. FORTESCUE FOX (Strathpeffer) read a paper on Articular Gout and its Treatment by Natural Sulphur Waters, describing first the acquired variety of gout, which is less common than formerly, and is generally seen in men of a stout and plethoric habit. Its history not infrequently includes antecedent rheumatism or rheumatic fever; urate deposits are not a marked feature, excepting in the "occupation gout" of coachmen and some others, and the disease either tends to visceral degeneration or, under favourable circumstances, to gradual extinction of symptoms and a healthy old age. On the other hand, hereditary gout is most often seen in spare, active, energetic men, and, not being a "diet disease," it is not to be cured by dieting. Dr. Fox has found in his experience at Strathpeffer Spa that both forms of gout are favourably influenced by courses of sulphuretted waters, but that a routine treatment is generally disappointing. Baths are often altogether contra-indicated, and in determining the diet and general treatment it is important to ascertain in each case whether the disease is acquired and dietetic or due to a hereditary perversion of tissue change. Gout in women is nearly always hereditary, and the articular symptoms present a wide range, varying from recurrent attacks resembling those met with in men to the gradual chronic enlargement of the terminal phalanges known as Heberden's nodes. Gout in young women is sometimes met with in the articulations, as recurrent attacks of synovitis in the knee

Digitized by Google

or shoulder, and may simulate "rheumatoid" arthritis. Arthritis, however, in Dr. Fox's view, is a term that should be reserved for degenerative disease of the joints. In this sense there is a form of gouty arthritis met with in later life in which one or more joints (shoulder, knee, or thumb) become affected with degeneration as a result of slight injury. This form of "local arthritis" must be carefully distinguished from the generalised disease.

A lengthy discussion ensued, in which many speakers took part.

Mr. WALTER BLAKER (Bognor) said that he himself was the subject of gout. He considered diet to be an important factor in keeping symptoms in check, three days of butcher's meat producing gravel. He had suffered much from headaches since residing at Bognor and found that these and other gouty troubles were worse when there was an excess of ozone in the air. He had derived much benefit for the gouty joint from the waters of Llangammarch in Wales and also from those of Buxton.

Dr. OLIVER (Harrogate) said that with respect to diet he was strongly in favour of largely increasing the fluids and the vegetable derived elements and of reducing the proportion of the animal food to a minimum.

Dr. FERGUSSON (Great Malvern) was in favour of reduced diet, increased consumption of fluids, and hot baths.

Mr. CUFFE (Woodhall Spa) had seen very hot baths produce gout at Woodhall though there was no sulphate in the water. He mostly met with the asthenic form of gout and observed that many of his gouty patients ate enormously of meat. He approved of a dietary containing little meat and very little alcohol. He strongly advocated the use of the cold spray and douche.

Dr. FORTESCUE FOX, replying, said that in Scotland much whisky was consumed, but there was not much gout. He did not favour any particular local application to the painful joints.

LIVERPOOL MEDICAL INSTITUTION.

Spina Bifida.—Strangulated Ovarian Tumour.—Pyosalpinx and Blood Cyst.—The Insanity of Conduct and the Tests of Insanity.

A MEETING of this society was held on April 30th, Mr. CHARLES H. SHEARS, Vice-President, being in the chair.

Mr. THELWALL THOMAS read notes of two cases of Spina Bifida. 1. The patient was a woman aged thirty-two years who had a very large lumbo-sacral sac, having a circumference of twenty-four inches, which had burst. In it were two nerve-like structures which were excised and proved to be simple fibrous cords with no nerve elements therein. The neck of the sac was sutured with a Saddler's suture, reef-knotted each time the needles crossed, and a catgut ligature tied around. She made an uninterrupted recovery. 2. This patient was a child aged six years with sacral spina bifida; it was globular, three inches in diameter, and the whole of the posterior wall of the sacral canal was missing. Excision was performed and the redundant dura mater and arachnoid removed. Continuous sutures united the arachnoid and the dura mater, and over the new canal were folded two flaps of fascia from the gluteus maximus as additional protection. Leakage occurred, so the wound was reopened and a small orifice closed by buried silk sutures. The wound then healed slowly notwithstanding an attack of measles. Mr. Thomas has found forty-six cases on record of treatment by excision, with a death-rate of 17·4 per cent. The Clinical Society's Committee's Report in 1885 gives Morton's own statistics: 50 cases, 9 unsuccessful, or 18 per cent. failures. The Clinical Society's 71 cases were treated by Morton's fluid with 27 deaths, or 38 per cent. They condemn excision on a published table of 23 cases with 7 deaths, or 30 per cent., apparently paying no heed to the cases treated before and those after the antiseptic era. If such had been done the result would have read: 16 cases before 1870, 6 deaths = 37 5 per cent.; 7 cases after 1880, 1 death = 14 2 per cent.; then their report might have been less directly adverse to excision.—Mr. R. W. MURRAY drew attention to the fact that hydrocephalus frequently followed upon the cure of spina bifida during infancy.

Dr. E. T. DAVIES read a case of Strangulated Ovarian Tumour. The patient was a woman aged forty-nine years who was known to have an abdominal tumour which was regarded as a myoma. Grave symptoms suddenly arose—diffuse peritonitis and stoppage of the bowels. At the end of a fortnight, the patient being collapsed and apparently moribund, laparotomy was performed. A strangulated ovarian tumour, universally adherent and quite black, was discovered and quickly removed. Recovery was uneventful.

Dr. E. T. DAVIES next related a case of Pyosalpinx and Blood Cyst. The patient was a woman aged twenty-nine years. She had been married eleven years and had three children, the last child five years ago. The menses were regular until two months ago, when she missed two weeks. There was a history of ruptured tubal pregnancy. At the operation pyosalpinx was found on the right side and blood cyst on the left. Sepsis followed with peritonitis, pus escaping from the lower angle of the wound. He thought the infection occurred in one of three ways: through the wound, from the stump of the tube, or from the gut, which was slightly injured near the cæcum.—Dr. IMLACH made remarks on the cases.

Dr. STANLEY GILL read a paper on the Insanity of Conduct and the Tests of Insanity. He pointed out that conduct was evolved from certain primitive movements, from random automatic movements, not psychically initiated, or rather those which seem to be independent of sensory stimulation; also from sensory-motor movements, which are conscious or unconscious, according as to whether they involve the cerebral cortex or no; and, lastly, from instinctive movements. He pointed out that these unacquired movements suffice to bring into play the motor mechanism of volition and thus supply experience. He said it was from experience so gained that we are enabled to direct our thoughts, feelings, and actions into the proper channels, and thus adapt ourselves to the particular environment in which we may happen to be placed. He defined conduct as the adjustment of the organism to its environment. The next part of the paper was devoted to the insanity of conduct, in which he showed the difficulties of defining insanity. He then drew attention to the three legal tests of insanity—namely, testamentary capacity, criminal responsibility, and a commission of inquiry as to the capacity of a person to manage himself and his own affairs. He did not believe in the test for criminal responsibility. Lastly, he quoted several cases to show that insanity meant something more than disorder of mind—namely, disorder of conduct.—Dr. IMLACH said that if conduct was three parts of insanity it was an argument against medical theories which attempted to explain insanity on animal physiology. Conduct was essentially a human act in accordance with reason or consciously opposed to it. The word could only be applied to the acts of an animal by analogy or to maintain a thesis. An animal always makes the best of its environment. Being what it is it could under given circumstances do no better. A man has a choice which the animal has not and which may lead him into a foolish or criminal act. When this freedom of choice has gone his actions are no longer strictly human. They stand apart as lunatic. An expert witness is able to point out facts which a jury might overlook, but the practical decision rests with the jury, for this is not a question of science but of common sense.—Dr. PERMEWAN, Dr. STANSFIELD, and Dr. ROSS took part in the discussion.—Dr. GILL replied.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—A dinner in aid of the funds of the City of London Hospital for Diseases of the Chest, Victoria-park, E., was held on Tuesday evening last at the Whitehall Rooms of the Hôtel Métropole. Lord Wolverton, who presided, showed in his speech that the income of the hospital was sadly below the necessary expenditure, and donations to the amount of about £2000, inclusive of 100 guineas from his lordship, were announced.

THE Prince of Wales made a surprise visit on Tuesday afternoon last to Guy's Hospital and spent a considerable time in inspecting the wards, pathological museum, college, and medical and dental schools. His Royal Highness expressed himself as much gratified by the report made to him of the satisfactory progress of the fund at the festival dinner, in support of which he has promised to preside. The impression that the fund is already adequate to the necessities of the charity is authoritatively contradicted at the Prince's request, as being likely to prejudice the success of the appeal.

Reviews and Notices of Books.

Twentieth Century Practice. Edited by THOMAS L. STEDMAN, M.D. Vol. IV.: Diseases of the Vascular System and Thyroid Gland. London: Sampson Low, Marston, and Co. 1896. Pp. 841.

THIS volume treats of diseases of the vascular system and thyroid gland. Dr. James T. Whittaker of Cincinnati writes the general article upon Diseases of the Heart and Pericardium, which occupies rather more than half the volume. It is no easy matter within moderate compass to treat with adequate fulness so large a subject. In Dr. Whittaker's work no important condition has been omitted, and its means of diagnosis, the elements of prognosis, its causation, and its treatment all receive attention. The important *rôle* assigned by "twentieth century" opinion to the influence of microbes in the production of endocardial inflammation is very properly emphasised, and the reader will find in these pages a sufficient presentment of current views upon the nature and management of diseases and disorders of the heart. After perusal of the article we can say so much in our desire to criticise as justly and as gently as possible—a task the difficulties of which we do not under-estimate. But there are some features in this article to which we take serious exception. As a work of reference it is not useful. In the 454 pages of the essay there is not a single reference. With very few exceptions we cannot gather whether the illustrations are original or copied, and in places secondary sources are mentioned in such a manner that if we knew no better we should regard them as original authorities. Thus, the illustration of pericardial effusion with displacement of the liver might have been executed for this volume did we not know that it was copied from Sibson's monumental article in "Reynolds's System of Medicine." On the other hand, a transverse section of the usual hypertrophied ventricle of aortic disease is carefully noted as copied from Ziegler's original. The dangers of information at second hand, are well illustrated in Dr. Whittaker's narrative of the discovery of coronary atheroma in its relation to angina pectoris. Dr. Whittaker gives Fagge as his authority. We here learn that Jenner suggested coronary occlusion as the cause of angina in a letter addressed to Heberden in 1778, but which he did not send out of consideration for the feelings of John Hunter, who suffered from the disease. We also learn that "Jenner (1775) first saw the calcification of the coronary arteries in an autopsy which was being made by John Hunter" (p. 439). With regard to these statements we cannot discover (1) that Fagge is responsible for this information, (2) that Jenner wrote an unsent letter to Heberden, and (3) that he saw calcified coronary arteries in any dissection made by John Hunter. As a matter of fact, Jenner's communication was made to Parry of Bath, whose essay was published in 1799, and the date of Jenner's letter cannot be fixed unless Dr. Whittaker has seen the original or some fuller excerpt, which, so far as we know, does not exist. With regard, moreover, to the dissection by John Hunter to which he refers, Jenner expressly states that to the best of his belief the coronaries were not examined in that case. "Fagge," again, relates the sudden death of Dr. Chalmers from angina pectoris, and no mention is made of the masterly essay on angina by Gairdner of Glasgow in "Reynolds's System of Medicine," the literary and scientific qualities of which render it a model for medical authors, and which was Fagge's source, as also Fothergill's, for the particulars of John Hunter's illness. Surely Gairdner's essay is as accessible as Fothergill's book! Fothergill, however, in the pages before us might pass for the original authority, notwithstanding his own express statement to the contrary. This is not, we trust, hypercriticism. We desire at all times to adhere to kindliness, checked by what we consider justice, as a sound canon of criticism, but these inaccuracies impair our confidence in a work which, without doubt, contains much valuable and correct information.

The section on Diseases of the Bloodvessels is from the pen of Dr. Arthur Ernest Sansom of London. Much of the material is the result of original investigation. There is a good account of the clinical history and gross and microscopic anatomy of acute and chronic aortitis. We do not, however, think that the evidence he adduces in favour of influenza being causal of the condition in some cases is conclusive (p. 460). His remarks upon the diagnosis of aneurysm of the aorta are excellent. The criteria for forming an opinion in these cases, so frequently obscure, but in which the necessity for coming to a correct conclusion is of great moment to all concerned, are given with a lucidity and practical insight very desirable in treating this subject. His views on the treatment of some of the conditions discussed are very judicious and sufficiently full to be of real service to those consulting this work. We would especially instance his rational indication of the place of digitalis in the treatment of the failing heart of atheroma. We observe (p. 546) that he classes the epileptoid phenomena of bradycardia with *petit mal*. For ourselves we think the weight of argument is with those who regard the cerebral phenomena of this condition as a mere index to the syncopal failure of the heart. The whole essay, however, will repay perusal, both by the expert and tyro, and is calculated to be a trustworthy guide in diagnosis and treatment.

In his article on Diseases of the Lymphatic Vessels Dr. Bertrand Dawson has in forty-two pages given as good an account of the affections of these vessels as any with which we are acquainted. Sufficient references are made to the anatomy and experimental and clinical pathology of the conditions in question to sustain the interest of the reader and instruct him by an indication of the *rationale* of observed cases. Mention is made not only of the results of direct obstruction of the lymphatic vessels, but also of the consequences of back-pressure, due to heart disease, in the various channels into which the thoracic ducts debouch. Cases which have been reported and in which there has been a leakage of chyle into the various cavities of the body are not common. Dr. Dawson has therefore been able to quote interesting particulars from original sources in some instances. To weigh cases, as Morgagni has it, is frequently more important than to count them, and the careful study of a few typical examples is often more instructive than the elaborate conclusions of fallible statistics. Dr. Dawson has weighed his cases well, and has produced a readable and instructive account of the diseases with which he has dealt. A complete list of authorities consulted is appended, with, in most instances, page-references, which is as it ought to be.

Diseases of the Thyroid Gland are very ably treated by Dr. George R. Murray of Newcastle-on-Tyne. His article on Myxœdema is especially valuable and contains much clinical and general information of the first importance, as we should expect from one who has devoted so much attention to a subject with the practical development of which his name is honourably associated. The slighter cases, most difficult of diagnosis, are considered, as well as those more pronounced with which we are now so familiar. Nothing is more remarkable in connexion with this disorder, recently so hopeless and obscure, than the diffusion of knowledge on the subject, so that facts but recently observed are as familiar to the profession as many connected with diseases much longer known and treated. This is probably owing to the close association of real benefit to the patient with learned discussion by the physician, conditions which do not, unfortunately, invariably go hand in hand. Thyroid extract, although so beneficial in its action, requires care

Digitized by Google

in its use in some cases, and the precautions necessary in its employment are set forth clearly in this article. With reference to Exophthalmic Goitre Dr. Murray argues strongly in favour of its production by an excess of thyroid secretion in the blood, just as myxœdema is due to its deficiency. There is undoubtedly much to be said in support of this view, but there are still, we believe, considerable lacunæ in the argument. As Dr. Murray states (p. 811), there are, indeed, some cases of ordinary goitre which exhibit one or more of the symptoms of exophthalmic goitre, but this is by no means the rule, and did the latter condition depend solely upon excess of thyroid secretion in the blood we should expect it to be observed more frequently than it has been at some period in the development of ordinary goitre. The earliest description of an undoubted case of exophthalmic goitre Dr. Murray attributes to an anonymous writer in 1816. There appears, however, to be considerable justification for the Italian synonym, "morbo di Flajani," for Virchow states, according to Warburton Begbie, that "Flajani was the first to notice the coincidence of goitre with lasting palpitation of the heart." Nor do we think Dr. Murray sufficiently acknowledges Dr. James Begbie's contribution to our knowledge of a disease which some desired at one time to call by his name. These are, however, small matters, and the use of a patronymic nomenclature has many objections. This article may be recommended as affording a very adequate account of the diseases with which it deals from the point of view of the physician, for surgical questions are not treated in detail.

After careful perusal of the whole volume, and excepting the strictures we feel it our duty to pass on the first article, we can recommend it as a valuable and trustworthy exposition of present-day views on the matters treated. There is a good general index and the publisher's work has been well done.

Recherches Bactériologiques sur l'Étiologie des Conjonctivites Aiguës et sur l'Asepsie dans la Chirurgie Oculaire. (*Bacteriological Researches on the Etiology of Acute Conjunctivitis and on Asepsis in the Surgery of the Eye.*) Par le Docteur V. MORAX de la Faculté de Paris, Ancien Interne des Hôpitaux de Paris. Paris: Société D'Éditions Scientifiques, 4, Rue Antoine-Dubois. 1894.

THIS work contains the results of the researches of Dr. Morax with regard to the application of bacteriological knowledge to ophthalmic surgery, especially in connexion with conjunctivitis, both as regards diagnosis and treatment. Accepting the bacteriological fauna of a normal healthy eye and appendages as given by Fick, Combert, Marthen, and others, he has paid special attention to the microbes that are found in conjunctivitis, and has tried to estimate their importance in connexion with the complications that may arise during the course of the disease or as the result of interference by treatment, especially, of course, in relation to the prevention of septic conditions following operative treatment. He comes to the general conclusion that acute conjunctivitis can only be classified according to its etiology, as the symptoms are in many cases almost, if not absolutely, identical, even when the etiological factor differs. He is convinced that contagious acute conjunctivitis occurs most frequently; it can be set up by inoculation and may be met with in all stages, from a comparatively slight attack of catarrh to the most characteristic purulent conjunctivitis, sometimes accompanied by corneal lesions. He looks upon the microscope as being the best diagnostic instrument in cases of blennorrhagic and other forms of infective conjunctivitis, whether they be the benign form, characterised by the presence of the pneumococcus, or the acute, associated with the streptococcus, especially when accompanied by a similar inflammation in the lacrymal ducts. In connexion with the aseptic treatment of diseases of the eye Dr. Morax points out that pathogenic microbes are very rarely found in the conjunctival *culs-de-sac* in the healthy condition, but that in certain diseases pyogenic organisms are often found. He points out, however, that the importance of the presence of bacteria in these sacs is sometimes unduly magnified and that a just appreciation of their importance in any special case can only be arrived at after a careful bacteriological examination. In all cases instruments used for operation should be carefully sterilised by means of heat. The only asepsis possible is that obtained by washing, and as in this class of cases this acts mechanically and not chemically he recommends the use of sterilised water, which does not irritate the eye and which gives quite as good results as chemical antiseptics. He recommends, of course, a careful and regular removal of all secretions, especially where there is any tendency to inflammation.

The work throughout is evidently based on careful observation, and although the observations of others have not been entirely passed over Dr. Morax relies to a very great extent upon his own experience as a basis on which to found his conclusions and recommendations.

Fear. By ANGELO MOSSO. Translated from the Fifth Edition of the Italian by E. LOUGH and F. KIESOW. Pp. 278. London: Longmans, Green, and Co. 1896.

THE name of the Turin professor is familiar enough to physiologists, and it is pleasant to meet the inventor of the plethysmograph and the well-known student of the cerebral circulation on more popular ground. The interest which his little book on "Fear" has aroused in its original Italian fully justifies its translation into English, and Messrs. Lough and Kiesow have done good service in the admirable translation here presented. Professor Mosso is much more than an accomplished physiologist: he shows himself a man of wide culture and a careful student of human nature; he is, further, master of a literary style at once luminous and picturesque. The strange combination of accurate scientific observation with real and unaffected sentiment and a remarkable power of vivid illustration make the book very unusual and attractive reading to the more phlegmatic temperament of our northern climate. It is an essentially popular book, which will interest the general reader as well as the physiologist and the physician, but accuracy has not been sacrificed to general effect. The author is a disciple of Darwin and Herbert Spencer, and not of Weissmann, but he differs from the first-named in several points. Many will agree with him that "The Expression of the Emotions" is not one of Darwin's greatest works, and it is natural enough that the progress of experimental physiology should offer simpler and more direct explanations of phenomena—such, for instance, as blushing, which Darwin attributed to the effect of self-consciousness acting on the vaso-motor nerves. The Action of the Central Nervous System, the Circulation in the Brain during Emotion, the Beating of the Heart, Oppression of Respiration, Trembling, the Physiognomy of Pain—these are some of the headings of the sixteen chapters in which Professor Mosso elaborates his subject. His illustrations and conclusions are always interesting, the final chapter on Education being particularly valuable and suggestive; and the book will not fail to captivate the reader by its style, even though he may not agree with its author in every respect.

LIBRARY TABLE.

Love Fugue. JON. B. FROST, Atlanta, U.S.A. London: The Roxburghe Press. Price 2*s.*—"So, departed shade of my weary Aunt, forgive my life! Forget or palliate my word! I but live a life for which occasion has not yet

Digitized by Google

occurred to be thankful." Why the Roxburghe Press have sent us this remarkable book we cannot say, for it is a perfect specimen of what Mark Twain calls hog-wash. The sentence we have quoted will give an idea of the chastened style in which it is written. Here is another gem: "You judge the conduct, did not observe the lady, her clean face, her eye brilliant with mischief, her fine forehead shown by the artful arrangement of her frizzes ..... she was embarrassed, if bad she would not have been abashed. Did you fail to observe that she was met by a motherly woman who may have been her aunt and borne from the depot in a private carriage? Everything indicated that she is vivacious—nothing that she is vicious." The opening words of the author are "I know not why I yet live." Neither do we.

Willing's British and Irish Press Guide for 1896, price 1*s.* published at 162, Piccadilly, contains the usual particulars concerning the press of the United Kingdom, together with a list of the principal colonial and foreign journals and a variety of general information.

Dod's Parliamentary Companion for 1896. London: Whittaker and Co., Paternoster-square. Price 4*s.* 6*d.*—The seventy-second edition of this well-known and indispensable book has reached us, carefully revised and brought up to date; it thoroughly deserves the popularity it enjoys.

JOURNALS AND MAGAZINES.

The *Practitioner* for May devotes its pages to vaccination in view of the coming 14th of May, the date upon which Edward Jenner performed the first vaccination on the body of one James Phipps. The editor remarks upon the extraordinary lack of appreciation shown by this enlightened country with regard to Jenner and his work. In this we cordially agree. A man who slays his thousands is honoured, and rightly, with dinners, orders, medals, and pensions; while he who has delivered his tens of thousands from one of the most horrible diseases known to humanity is passed by as no one. Perhaps the greatest praise and most striking commentary upon Jenner's invaluable services is to be found in the recent epidemic at Gloucester, and we would suggest (1) the inscription on the pedestal of the statue of Jenner in Kensington Gardens in large letters of—(*a*) the numbers of those attacked with small-pox; (*b*) the deaths; and (*c*) a tabular statement showing the proportion of deaths to vaccinations; while upon the other side of the pedestal should be the names of the anti-vaccination guardians and the members of the anti-vaccination societies—"These are raging waves of the sea foaming out their own shame ..... murmurers, complainers, walking after their own lusts." In the original communications Dr. Monckton Copeman writes on Small-pox and Vaccinia, their Manifestations and Inter-relations in Man and the Lower Animals; Dr. Buist upon Natural and Cultivated Vaccine; Dr. Colcott Fox upon the Accidents of Vaccination, a most valuable paper; and Dr. Edward Seaton upon Compulsory Vaccination from the Legislative Point of View. Dr. Edwards's paper upon Vaccination and Small-pox Statistically Considered ought to be in the hands of every guardian. The hero of medicine for the month is, of course, Jenner, and the medico-literary causerie, Small-pox before Vaccination.

The *Quarterly Medical Journal for Yorkshire and the adjoining Counties* has an interesting paper by Dr. Norman Moore upon Tuberculosis and an admirable plea for greater purity in medical nomenclature by Dr. C. A. Greaves. Dr. Crochley Clapham cites an interesting case of Congenital Absence of the Uterus. Dr. Preston King has a good paper upon Bath as a Health-resort.

The *Birmingham Medical Review.*—Mr. Oliver Pemberton has an appreciation of the late Sir William Savory worthy both of the writer and his subject. Mr. Jordan Lloyd discusses the Curability of Cancer of the Uterus, his conclusions being summed up in the words, "Operate early if you can." Dr. Simon writes upon the Treatment of Typhoid Fever, and Dr. Sydney Short reports a very interesting case of death from some mysterious cause, probably cerebral. Dr. James Russell reports a case of Cerebral Thrombosis with some very Unusual Symptoms. There is an interesting "note" upon Provident Medical Aid.

In the April number of the *American Journal of the Medical Sciences* Dr. J. J. Thomas of Boston discusses Twenty-nine Cases of Diphtheritic Hemiplegia recorded by various authors, and describes two cases which had come under his own observation. Dr. J. H. Etheridge of Chicago gives a very full account of three cases of ovarian abscess caused by the micrococcus lanceolatus (diplococcus pneumoniæ, pneumococcus of Fraenkel and Weichselbaum). He believes that although this organism is a well-known cause of many inflammatory processes there has not until now been any record of ovarian abscess due to it. Dr. Chittenden and Dr. Mendel conclude their articles on the Influence of Alcoholic Drinks on the Processes of Digestion.

The *Edinburgh Medical Journal* for May has two instructive articles on Osteomalacia, in one of which Dr. James Ritchie summarises the results of numerous observers and describes in detail several cases attended by himself. One of the patients took both white and red bone marrow without any apparent benefit, but improved very much after undergoing oöphorectomy. Dr. T. M. Allison gives an elaborate account of another case of the same disease in which there was visible improvement at the end of a week from the commencement of the bone-marrow treatment, and after seven months the patient's condition was greatly changed for the better. Dr. J. W. Ballantyne writes on Congenital Teeth and Dr. W. G. Sym on Ophthalmia Neonatorum.

Journal of Mental Science. April, 1896.—From a clinical point of view the current number of this quarterly perhaps does not present so many features of interest as usual. One of the articles is original in more than one sense. It emanates from the pen of a gentleman who suffered from temporary mental aberration, from which he happily recovered, and he depicts in vivid language the strange impressions and visual hallucinations which troubled his perverted mentality. Dr. Hyslop contributes a suggestive paper on "Pseudo-general Paralysis" which is referred to in another column of our present issue. There is no doubt that his argument is well founded when he states that many cases, of which he gives examples, are really not cases of general paralysis *per se*, but rather of special paralysis with insanity. A temperately written article on the occurrence of insanity amongst the prison population ought in a measure to remove much of the misconception that appears to exist regarding the origin and causation of mental disease in prisons. The psychological and therapeutic retrospects, as usual, contain valuable information.

MESSRS. N. M. ROTHSCHILD AND SONS have sent 50 guineas to the Royal Hospital for Diseases of the Chest, City-road, E.C., towards the fund being raised in connexion with the festival dinner to be held at the Hôtel Métropole on May 26th.

MEDICAL MAGISTRATES. — Mr. Sydney L. Richardson, L.R.C.P. Edin., M.R.C.S. Eng., has been appointed a Licensing magistrate for the district of Queanbeyan, New South Wales.—Mr. Leonard L. Seabrook, M.B. Ch.B. Adel., has been appointed a Justice of the Peace for South Australia.—Mr. R. A. H. Williams, L.R.C.P., L.R.C.S. Edin., of Fermoy, has been appointed by the Lord Chancellor to the Commission of the Peace for the county of Cork.

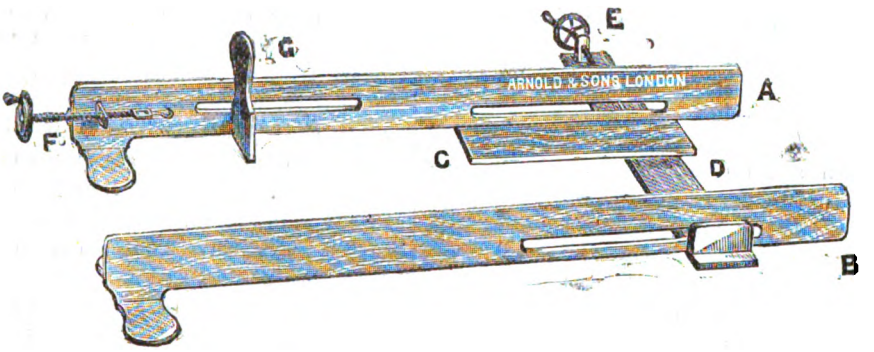
New Inventions.

IMPROVED HIP-SPLINT.

APPRECIATING the difficulty of obtaining bony union in all fractures about the hip-joint (and this I take to be due to want of proper apposition with consequent want of proper fixation of the bony fragments and neglecting to fix the entire pelvis during treatment), the splint I have had made for me by Messrs. Arnold and Sons of West Smithfield meets all these requirements. It consists of two long side-splints A B, with sliding foot-piece G, and by thus fixing both lower extremities the pelvis is fixed. Extension is obtained by means of screw F. The hip-joint is prevented from sinking into the bed by the back-splint C, which is movable along the slot. To obtain absolute approximation of the fragments in capsular fractures pressure must be made on the great trochanter of the injured side, and this is provided for by the screw E, which, when turned gradually, approximates the upper ends of the two long side-splints. The splint is reversible, so that it may be used for either side of the body; also, as it is detachable, one side-splint can be used if required.



A. HERBERT BUTCHER,
Surgeon to the Birkenhead Borough Hospital.

THE "UNIVERSAL" TEAPOT.

TEA properly made should be an infusion and not a decoction, but the vessel in which this beverage is ordinarily prepared is more adapted for the latter process than the former. In our issue of Nov. 30th, 1895, we described a new tea infuser from which we obtained very satisfactory results, but the peculiarity of its construction rendered it practically useless unless a full pot of tea was required. The object to be aimed at in the construction of a really good teapot is, of course, the separation of the spent tea leaves from the hot infusion; and this Messrs. George Donald and Co., of Central-chambers, Glasgow, seek to accomplish by attaching to a chain, which passes through the lid of the pot, a small vessel for containing the tea (see illustration). This vessel or infuser is allowed to rest at the bottom of the pot until the tea is "drawn" and is then elevated into the lid by means of the chain and kept in position by a pin passing through one of the links. The "Universal" teapot is made in brown ware, stone ware, and china, the best materials of which teapots can perhaps be made; and for the end in view—namely, the making of an infusion and not a decoction—the contrivance is almost all that can be wished. We would point out, however, that it is far from desirable to use a brass chain however heavily it may be plated with silver (in the present instance it is triple plated), as the contact of the two metals is likely to set up an electrical action. A chain made from pure aluminium would be far preferable.

NUTRIENT SUPPOSITORIES.

THE nutrient suppositories for rectal feeding manufactured by Messrs. Parke, Davis, and Co. are about an inch long and half an inch in diameter at the base. Each contains about 125 grains of fresh lean beef almost entirely peptonised. They are firm in consistence and have a smooth, dry surface.

GELATIN CAPSULES.

MESSRS. PARKE, DAVIS, AND CO., of 21, North Audley-street, Grosvenor-square, have forwarded to us samples of their improved empty gelatin capsules, by the use of which the difficulties of administering unpalatable powders are reduced to a minimum. The capsules are made in ten sizes, differing greatly in their several dimensions, but all on the same principle. The larger sizes very much resemble short, round-ended, glass test-tubes, such as are used by chemists everywhere, but are without the ordinary everted border, and have a well-fitting cover, consisting of a similar but shorter tube sliding over the other. For administration by the mouth they are made in seven sizes, the smallest of which is about as large as an ordinary three-grain pill, and will contain either three-quarters of a grain of sulphate of quinine or one grain of powdered aloes or rhubarb. The largest of these is about a third of an inch in diameter and one inch long when closed; it will hold eight grains of sulphate of quinine and about ten grains of powdered aloes or rhubarb. By means of them it is also easy to swallow nauseous uncoated pills without tasting them. The capsules are hard but elastic, they are smooth, the covers fit well, and the shape is convenient for being swallowed, but if held in the mouth they dissolve before long. There are also three sizes having a tapering end for rectal administration and three for veterinary and vaginal capsules. The latter are convenient for the local application of medicated cotton. A special filler is supplied for powders and pills.

THE LANCET.

LONDON: SATURDAY, MAY 9, 1896.

THE action in which Mr. and Mrs. ARTHUR KITSON claimed damages from Dr. and Mrs. PLAYFAIR for publishing a slanderous statement concerning the female plaintiff has now come to a definite conclusion. At the trial before Mr. Justice HAWKINS the defendant denied publication and claimed privilege. No plea of justification was put on the record, and consequently the presiding judge would not allow charges aspersing Mrs. KITSON'S character to be made in Court. Of course, it was impossible to present the case to the jury without bringing out the salient facts upon which the alleged slander was founded. It is not necessary for our present purpose to give a detailed account of these facts. Suffice it to say that Mrs. KITSON, who had been in England for over a year—her husband remaining abroad—suffered from metrorrhagia for some weeks. At her suggestion, or with her consent, her medical attendant sought the aid of Dr. PLAYFAIR, whose wife was the sister of Mr. KITSON. On two occasions a direct examination was made, and on the latter a substance was removed from the uterus which Dr. PLAYFAIR judged to be the product of a recent conception. In a correspondence on the subject Dr. PLAYFAIR informed Mrs. KITSON of the opinion he had formed and intimated to her that he could only keep intact the seal of professional secrecy on condition that she left London and broke off social intercourse with his immediate family circle or that she could show that she had seen her husband within a period which would remove the grounds of the charge of unchastity. From first to last, though she had to face as terrible a situation as it is possible to imagine a wife and mother to be placed in, Mrs. KITSON persisted in her innocence. Dr. PLAYFAIR not finding his suggested terms of compromise accepted informed his wife and also Mrs. KITSON'S brother-in-law of the facts and the deduction he had drawn from them. This was the slander complained of and on which issue was joined in the High Court.

Although the case is one of profound interest from a medical and pathological standpoint we intend at this moment to discuss it only on the lines presented to the Court. At the trial the verdict went against the defendant, the jury finding that there was publication with interested motive and express malice on the part of Dr. PLAYFAIR. An appeal was entered against the verdict, but when the time arrived for it to be heard terms were agreed upon between the parties to the suit and thus the litigation ceased. It is not within our province to criticise the questions of law as laid down by Mr. Justice HAWKINS at the trial or to challenge the findings of the jury. The former must be taken as an equitable presentment and the latter to embody the opinion of twelve unbiased men upon their oath. But beyond the four corners of the law there is ample field for meditation. Never was the question of professional etiquette more forcibly presented. It must be allowed that there is no written code to guide a practitioner in every case in which his discretion and judgment are evoked. There are those which it would be subversive of all moral rule to divulge. There are those which it is his bounden duty to disclose; but on the frontier between compulsory secrecy and publication there are many instances every one of which must be decided upon its particular merits. It may be held to be a safe formula that, unless there are overpowering reasons to the contrary, a patient's secret should be held inviolate by his medical adviser almost, if not quite, as binding as the confessional of the Roman Catholic priesthood. Where it involves the actual commission of crime, morality and justice require the breaking of a confidence which the recipient should never have been asked to accept. Where it is supposed an illegal act is contemplated the line of action is not so clear. Mr. Justice HAWKINS had in mind such a contingency when he asked Sir JOHN WILLIAMS what he conceived would be his duty if consulted professionally in a suspicious case of criminal abortion. Sir JOHN WILLIAMS without hesitation replied he would communicate with the Public Prosecutor. "I am not so sure you would be doing right," came the rejoinder of the learned judge. There is much to be said on both sides. In the first place, it is obviously every one's duty to prevent the immediate commission of a crime and to deter from more remote repetitions of such. Moreover, failure to guide the hand of justice may strengthen the evil intents of ill-doers. We should say, on the other hand, that unless the information possessed by the medical practitioner is sufficiently weighty to make it reasonably certain that the allegation will be sustained it is better to observe a discreet silence.

Reverting to the basis of our special commentary we feel it our painful duty to assent to the proposition that Dr. PLAYFAIR did not act as discreetly as he might have done. Was it wise to place such alternatives before Mrs. KITSON as it was proved in evidence he did place? To a statement in one of Mrs. KITSON'S letters to him suggesting, though not defining, an explanation of her innocence he lent a willing ear, although there was no evidence forthcoming that there was reasonable probability of the existence of such grounds of exculpation. We refer to the question of a visit to England by Mr. KITSON. It seems that at that time Dr. PLAYFAIR was struggling between two opposing forces—the one compelling him, out of human pity and from a sense of professional duty, to keep secret the conclusions at which he had arrived; the other to shield his family from the pollution which, he thought, further social intercourse would entail. Whilst recognising his perilous position it would have been well, we think, had he sought in confidence the help and advice of some distinguished members of the profession. In so doing he would have proved better than in any other way that midst all his undoubted difficulty and trouble he was striving to act justly between man and man. Although we are unable to endorse as fully as we could have wished the course and

Digitized by Google

tenor of his action, we cannot but regret his misfortune and tender the sympathy such misfortune claims.

FOR some years past the study of the errors of refraction in the eye has been earnestly pursued in America. The journals devoted to ophthalmology in that country, which are many and excellent, are remarkable for the number of important articles they contain on the symptoms and methods of treatment of the defects of vision arising from these errors. They discuss at great length and with much ingenuity not only the ordinary defects of myopia, hyperopia, and astigmatism, but those conditions of imperfect vision that are dependent upon, or that are associated with, defects of the nervo-muscular apparatus of the eye and which are capable of being alleviated or altogether remedied by appropriate treatment with lenses and prisms. These articles, primarily addressed to the instructed ophthalmologist and presupposing a thorough and complete medical education, are, of course, accessible to the public and therefore to the optician. Partly as the result of knowledge gained from such sources, partly from observation of the successful means adopted by experts and of the trials and essays, and it may be of the failures of such experts in difficult cases, and partly from information acquired by the desire to carry out in an intelligent manner the orders of the surgeon, the optician has of late years stepped in and now not only claims the selection of glasses as a branch of his work for which he believes himself to be specially fitted, but contends that it is no part of the duty of the medical practitioner to treat such cases at all, especially since in most cases he has neither the apparatus required for testing vision with accuracy or the knowledge which would enable him to select the glasses that would remedy the defect. As a matter of fact, few practitioners in the country, or even in large towns, feel themselves to be competent to undertake the treatment of defects of the eye requiring the use of glasses, and as a rule send such cases to some friend in whom they have confidence and who is practising exclusively as an ophthalmic surgeon. But, as an American contemporary remarks in a leading article devoted to this subject, it is certain that we are entering upon a prolonged period of controversy and even warfare with the opticians. In the State of New York a determined attempt, it is said, is being made to secure the passage of a law which shall recognise jewellers and spectacle vendors as "official refractionists," whilst the physician or professed ophthalmologist is to be relegated to the position of one who shall treat only diseases of the eye whether by medicines or the knife.

In England the contest has not arrived at quite so acute a stage, and we are inclined to think that it may, with a little generosity of feeling and action on both sides, be altogether averted. For one thing, it is quite certain that no legal enactment could be made so stringent as to prevent a man from walking into an optician's shop, trying for himself a pair of convex or concave spectacles, paying for them, and walking out again. He takes the risk of the numbers being correct and may or may not be helped or aided in his selection by the optician with whom he deals. If after one or two trials he finds them unsuitable he probably applies to an ophthalmic surgeon and no harm is done. Hundreds of pairs of glasses are thus purchased daily, and it is difficult to see what exception can be taken to the transaction. On the other hand the optician entirely misses the point of the discussion when he contends that he is as capable as the ophthalmologist of determining the glasses that are required in any given case. Freely according to him the benefit of the doubt that he can supply the appropriate glasses as well as the ophthalmic surgeon can, the real question is, Are glasses required at all? To prescribe correct concave or cylindrical glasses for a case of short sight is not a difficult matter, and any intelligent man might learn to do so in a few months; but it is impossible to impress too strongly on the optician the fact that although the selection of appropriate glasses is an important matter, it by no means comprises the whole treatment of myopia. The case may be one in which a delicate child from a spirit of emulation is working hard and is actually developing the defect. Would any optician say to the parents: These glasses give your child perfect vision, but I strongly recommend you *not* to purchase them? We apprehend not. Yet this is precisely the advice that every ophthalmic surgeon has to give, not once or twice, but repeatedly to those most interested. Avoid glasses, he will say; send the child into the country and do not let him look at books. Again, there are various conditions of the eye which require a quite special medical training to recognise, and which are temporarily benefited by glasses, but which, if treated with them alone, are likely to lead to loss or great impairment of vision. Let us take glaucoma, for example. A sufferer in the earlier stages applies to an optician, who with his tests makes out accurately enough the number the patient requires. Within a month the latter becomes dissatisfied and applies to another optician, who supplies him with another and stronger pair of glasses with the same results. At length he calls in the aid of an ophthalmologist, is then told the nature of the disease, and is informed that an operation is imperative—an operation that might have been avoided had he been in the first instance examined by an expert. In many—nay, in most—instances the physical condition of the patient, the family history, the nature of his work, and, still more important, the internal changes which become apparent under the ophthalmoscope are all duly weighed by the surgeon and their influence for good or bad considered before glasses are prescribed. How can the most experienced optician discuss these points with his customers? It is quite true that the average practitioner, who during his student career has given but little attention to the eye, would certainly be beaten by a practical optician in the selection of appropriate glasses; but we would infinitely rather rely upon the judgment of such a practitioner than upon that of any optician as to whether glasses should or should not be worn.

Taking the lowest and most commercial aspect of the question, we cannot see that the optician would lose by sending to a duly qualified ophthalmic surgeon the cases that apply to him for relief. No ophthalmic surgeon in Great Britain supplies glasses; the patient must obtain them from some optician, and it would be rare indeed for

Digitized by Google

a patient sent by an optician to be directed to apply to some other tradesman. We are inclined to think that English opticians will make no attempt to encroach beyond the reasonable limits of giving low powers of concave and convex glasses, with astigmatic correction, if they feel themselves competent to determine the amount, and will send all high degrees of these defects and all those exhibiting unusual conditions to those who are alone properly able to deal with them—to wit, the ophthalmic surgeons—and we sincerely trust that no rivalry in any way resembling that which appears to be in progress in America will take place in England.

ALTHOUGH it is too early yet to estimate the full extent of the outbreak of small-pox in Gloucester and its effect on the material prosperity of the city enough is already known to indicate that both directly and indirectly a heavy price is being paid for years of neglect of the primary safeguard against such visitations. Were it not so pitiful we might dwell upon the irony of fate which has brought into conjunction this scourge and the eve of the centenary of JENNER'S first vaccination and in a place so near to the scene of his patient and fruitful investigations. The latest returns gave a total of some 1600 cases of small-pox notified in the city during this epidemic, the height of which seems to have been reached in the middle of last month, when in one week there were no fewer than 211 cases notified. This for a city of about 40,000 inhabitants is sufficiently striking, whilst the weekly return of deaths shows that the mortality has been exceptionally high. Nor is it disputed that amongst the victims there have been a large number of children, which is in contrast with modern experience and doubtless recalls the incidence in times gone by when the child community had not received the protection afforded by JENNER'S discovery. The energetic measures that are now being taken to reach the children who are still unvaccinated, although late, may lessen the extent of the plague, whilst the natural decline of the disease as summer advances must raise hopes that the city may be free from it before the autumn comes round.

Small-pox has prevailed in England for the past five or six years, and Gloucester, like many other towns, has not been free from sporadic cases introduced by the tramp class — those nomadic distributers of contagion. But Gloucester, like some other places, had a weak place in its armour. So long as cases were few and scattered the measures of isolation &c. adopted by the sanitary authority could limit the spread of infection within the city; and the comparatively mild experience of Leicester two years ago may have encouraged the opponents of vaccination in Gloucester in the belief that they were equally secure. They have had a rude awakening from this dream, and some day—no matter how vigilant they may be—Leicester and other unvaccinated communities will receive the same lesson. For it has been demonstrated in Gloucester that, if the first line of defence against small-pox be abandoned, the provision of hospital isolation and the means for supervision of infected households must be on a scale far more extensive than is requisite in towns where the children are protected by vaccination. It is said that the rapid extension of the disease in the month of February was due to school infection; but so rapid was it and so widely diffused that the ordinary measures for coping with epidemic disease failed to have any influence in checking it. We may dismiss as ridiculous the argument that the disease has been fostered by defective drainage. It has been shown by the medical officer of health that the southern part of the city, in which it has mostly been prevalent, is the least crowded and the healthiest district, being free from diseases attributable to such defects. There is, however, a source of further infection in the hospital which has been rapidly extended to meet with the requirements. It is futile to carry out isolation if thereby a fresh focus of infection is established, and we trust, for the sake of the city, that the sanitary authorities will seriously consider the propriety of retaining these buildings. There has been no lack of earnest endeavour to do all that is possible to provide the means for isolation, and it seems particularly ungracious to criticise these well-meaning efforts; yet there is so much evidence in favour of the view that small-pox hospitals may *per se* disseminate contagion that it is impossible not to regard with some anxiety the retention of buildings for that purpose within a few hundred yards of inhabited dwellings.

The lesson which Gloucester has learnt may, we trust, be impressed on other towns. Small-pox can be controlled by efficient vaccination and revaccination, but if these precautions are disregarded there should be provided such machinery and such an amount of isolation accommodation to meet emergency which may at any time arise as would in themselves constitute a heavy standing tax upon the community. But wherever the second alternative is adopted as the sole method of coping with small-pox, it will have to be done with the full knowledge that the cost will not be one of money alone but will include the inevitable sacrifice of many of those who have not been afforded the personal protection that vaccination gives.

Annotations.

"Ne quid nimis."

THE APPEAL OF THE APOTHECARIES' HALL OF IRELAND TO THE PRIVY COUNCIL.

THE hearing of this case by the Privy Council—that is, the matter of an application by the Apothecaries' Hall of Ireland for the appointment of examiners to assist at the qualifying examinations which are held by the said Hall, which application has been refused by the General Medical Council—is fixed for Monday, May 11th, at eleven o'clock, in the Council Chamber, Whitehall. As the first instance of an appeal from the judgment of the General Medical Council to the Privy Council it cannot fail to be interesting, apart from the importance of the continuance or otherwise of the Apothecaries' Hall in the medical economy of Ireland. The proceedings will, of course, be open to the public and the Press.

KISSING THE BOOK.

As long ago as November last reference was made in our columns to a scene at a Sussex police-court, Petworth, between the Rev. Rowley Lascelles, rector of Graffham, and

Digitized by Google

the chairman of the bench of magistrates because the former declined to take the oath in the customary unclean fashion. Mr. Lascelles was in the witness-box at a neighbouring police-court, that of Midhurst, last week, and it is to be regretted that the chairman of the bench thought fit to make similar and unjustifiable comment upon Mr. Lascelles' refusal to be sworn except in the Scottish fashion. The magistrate's clerk observed, "But you are a clergyman of the Church of England?" to which the witness very properly replied, "I refuse to answer any such question and claim to be sworn in the Scotch fashion." The chairman then said, "Are you not an Englishman?" a question which also was rightly disregarded. This sort of thing is of no importance in the case of a gentleman who is strong and sensible enough to form his own opinion and to stand by it despite official sarcasm, but it is not right that an ignorant or ill-informed person should run the risk of a bullying at the hands of those whose duty it is to administer justice in the exercise of his undoubted and unquestionable prerogative.

TOURISTS AND IMPURE WATER.

THERE is not a more important question affecting the well-being of the tourist than that of the water supplied to him. The quality of the water at places visited by tourists, holiday-makers, and others is so frequently an object of suspicion as to lead them to avoid it altogether for drinking purposes. It is to be feared that the doubts thus often entertained as to the fitness of the water-supply at many hotels and health resorts, and especially abroad, are not without a reasonable foundation. It is well known that illness amongst travellers is very often directly traceable to a bad water-supply. We do not refer to cases where typhoid fever or cholera has been the result, although, of course, their occurrence from this cause is well known, but to certain minor complaints, such as sore-throat, boils, &c., where the water is probably also the *fons et origo mali*. There is no doubt, further, that a mere change in the quality and composition of the water consumed has an important influence, it may be favourable or unfavourable, upon the health. The question then arises, What shall the tourist or the individual seeking health and change of environment drink? He has been recommended on good grounds not to drink a strange water unless it has been boiled as in the preparation of tea and coffee. But these are not substitutes for the plain and pure water which he requires. The use of filters cannot be recommended unless their working is carefully managed and supervised by a trustworthy person, since with many kinds of filters it has been shown that this precaution has resulted in something worse than if it had not been applied. We think in this connexion that the germicidal effect of carbonic acid gas dissolved under pressure in water has been to a large extent overlooked. Mr. Hankin showed some two years ago that the carbonic acid gas in aerated water acts as a poison to the microbes, so that a bottle of aerated water which was teeming with bacteria when first made is generally perfectly free from active bacteria at the end of a week. The aerated water experimented with was bottled in India under a much higher pressure and temperature than is the case in England, and it is considered probable that in the Indian aerated water these conditions greatly aid the action of the gas. The results appear to lead to the conclusion that the virulence of the cholera, typhoid fever, and other microbes is thus destroyed and the risk of infection from carbonated water can be avoided if it is kept a week or more before use. These observations suggest that a carbonated *natural* mineral water is quite safe and trustworthy for drinking purposes, since previously to coming to the surface it is under an extremely high pressure of carbonic acid gas, to which pressure, furthermore, it has been subjected for a very long time. These are precisely the conditions, according to the researches alluded to, under which bacteria would be destroyed, and this effect may in some measure account for the advantages which a natural mineral water possesses over artificially aerated waters. Another important point connected with the safety of natural aerated waters for drinking purposes is that as a rule before being bottled the water is allowed to stand so that the iron may be oxidised and allowed to settle. This process not only makes the water clear and bright, but has an important purifying influence upon the water both in regard to organic and organised matters. There is no lack of supply of natural aerated waters on the Continent, where, also, they are comparatively cheap; and it would seem, therefore, that if these views be correct the visitor could confidently employ them for drinking purposes. At places of health resort at home, also, should any doubt be entertained on the same score, natural aerated water, it is reasonable to conclude, may be used with the same confidence. The subject is well worth attention in view of the approaching holiday season.

"PYGMY RACES OF MEN."

PROFESSOR FREDERICK STARR'S article on "Pygmy Races of Men" in the *North American Review* contains much interesting information regarding a curious and fascinating subject. The existence of pygmies has been known from the earliest times, and allusions to them are found in the writings of Homer, Herodotus, Aristotle, and Pliny. Although many of these allusions contain a fabulous element and are destitute of any scientific accuracy they at least represent a widespread belief which probably had some basis of fact as its foundation. In view of recent discoveries it is interesting to find that one of the most detailed and precise accounts of the ancient pygmies locates them in the deserts of Libya. De Quatrefages, quoted by Professor Starr, asserts that "the ancients had information more or less inexact, more or less incomplete, but also more or less true, concerning five populations of little stature, from whom they made their pygmies. Two were situated in Asia; the third toward the sources of the Nile; the fourth toward the East, but not far from the preceding; the fifth still in Africa, but entirely in the south-west." Modern travellers have confirmed these accounts, which have often been received with much incredulity. Schweinfurth found the diminutive Akkas at the court of Munza, King of the Monbuttu. Du Chaillu found the little Obongos in the Ashango country. Finally, Stanley put an end to all doubts on the subject and established beyond cavil the existence of various pygmy races in the interior of the African continent. The best known of the African pygmies are the Akkas, who are thus described by Stuhlmann writing so recently as 1893. He described them as "averaging 1·25 metres in stature, with light brown skin tinged with reddish-yellow. They have a round head, flat nose, prognathic face, and woolly brown hair. The beard is scanty, but a growth of light down-like hairs covers the whole body. They are characterised by a penetrating and disagreeable odour. In character they are cunning and cruel, with thievish propensities and many childish traits. They live in slight temporary shelters and dress scantily in leaves. They have no characteristic tattooing and no ornaments, but sometimes bore the upper lip. They are hunters and use the bow and poisoned arrows. Though sometimes cannibals, they are so but to a moderate degree." These pygmy tribes are generally found in isolated groups surrounded by populations of different ethnic origin and of normal stature. As might have been conjectured the pygmies usually occupy the less

Digitized by Google

favoured districts. They are by no means confined to Africa, but are found in India, the Malacca peninsula, Annam, New Guinea, the Andaman Islands, and Japan. With some divergencies of type, they usually present four leading characteristics—viz., small stature, dark skin, woolly hair, and short, round skulls. The Mincopies, or pygmies of the Andaman Islands, represent a well-marked type. They are even shorter in stature than the Akkas. The head is very large, the body well formed and developed, the hands and feet small and delicate, the skin black, and the hair black and woolly. They are active and vigorous, but short-lived. Quite recently the existence of a race of dwarfs in the Atlas Mountains of Southern Morocco has been demonstrated. They are reported to be about four feet high, with a "mahogany" complexion and short woolly hair. They are active and brave, skilled at single-stick and in hunting ostriches, and have some knowledge of tinkering and cobbling. They live on milk and camel-flesh. Remains of pygmy races in Europe have been found in the Crimea, Kazan, Astrakhan, Sicily, Sardinia, near Naples, and elsewhere. Sergi, the Roman anthropologist, finds evidence of a pygmy population at present existing in Russia and Italy. His theory is that there was an early migration of pygmies from Africa northward into the Mediterranean islands, Italy, and Eastern Europe. The Nanos of the Pyrenees are only about four feet high. They have a red complexion, red hair, a round face which is as wide as it is long, prominent cheek bones, a flat nose, and eyes like those of a Chinaman. Opinions differ as to whether these Nanos are simply cretins or the last remnants of a vanishing race. Traces of pygmy races are not wanting on the American continent. The remains of ruined buildings in Yucatan and Central America are suggestive of pygmy origin. "Various writers have commented upon little Mexicans. In 1882 a band of little people invaded British Honduras. They were from four feet to four feet six inches in stature, and are said to be warlike, to make human sacrifices, to use the blow-gun and poisoned arrows, and to be makers of Panama hats." It is evident that the existence of pygmy races has passed out of the region of myth and fable into that of history and science. Our information regarding these strange races is still incomplete and inexact, but it is being steadily augmented and brought into line with accepted results in biology and anthropology. The facts already educed suggest many interesting reflections, but perhaps raise more problems than they solve. It seems clearly impossible to regard the pygmy races as owning a common origin, although their tendency to conform to a single fairly well-defined type is very curious. Is their case one of degeneration owing to some special circumstances of climate and environment, or do they represent a remnant still remaining in a stage of development long since left behind by the rest of the human species? We cannot say with certainty, but such questions may yet become capable of solution when our information on the subject has become more extensive and exact.

THE PLAGUE AT HONG-KONG.

IT is evident that the inability of the Hong-Kong sanitary authorities to eradicate the bubonic plague with which the colony has so long been afflicted must in some measure, at all events, be due to the numerous body of irregular practitioners, chiefly Chinese, who through ignorance or carelessness fail to report the cases of the disease that they are called in to attend. Any persons who choose to do so are apparently at liberty to practice medicine on the island, the law under ordinary circumstances being powerless to interfere; but good sometimes springs out of evil, and, as will be seen by the following extract from the *Hong-Kong Daily Press* of March 4th last, the existing epidemic has led to the infliction of well-merited (if inadequate) punishment upon one member of the unqualified fraternity. "A Chinese doctor named Wong San Chan, of 307, Queen's Road West, was charged at the Police-court yesterday with failing to report a case of plague. The defendant attended the patient, Ng Oi, on the first-floor of 14, Pokfulam-road, and when death from plague took place the doctor failed to report it. Dr. Atkinson, who examined the body, said there was a swelling in the deceased's neck. The defendant said he did not know the law, and further excused himself by saying that his patient suffered from fever and he did not see a swelling in the neck. The magistrate, Mr. T. Sercombe Smith, fined the defendant 25 dols. or a month's imprisonment." It is possible that with skilled medical assistance the hapless Ng Oi might have survived and be still in the enjoyment of his first-floor in Pokfulam-road, but manifestly the presumable Chinaman with a name like a chemical symbol never had the chance, for the nature of his disease was not even recognised by the ignoramus Wong San Chan.

"X" RAYS AS A DEPILATORY.

ALL sorts of physiological effects produced by "x" rays have been recorded since the Roentgen boom, but the announcement that they are likely to cause baldness is calculated to spread dismay amongst those who have been experimenting closely with the Crookes's tube. In a preliminary experiment to ascertain the possibility of photographing a bullet in the head of a child it was found that twenty-one days after the experiment all the hair came out in the region exposed to the "x" ray discharge. If the time that elapses before positive baldness was effected could be reduced what an incalculable benefit would Roentgen's discovery confer on shavers. Thus to remove the beard would only require the placing of a Crookes's tube for a few minutes over the chin before retiring to rest, when next morning the ordinary application of soap and water would complete the operation! Under these circumstances the "new barber" may not impossibly be one of the many outcomes of the "new photography."

"PSEUDO-GENERAL PARALYSIS."

IN a recent number of the *Journal of Mental Science* is reprinted an address on this subject delivered by Dr. Theo. B. Hyslop at the February meeting in Cambridge of the Medico-Psychological Association. Dr. Hyslop begins by disarming any criticism which might be offered with regard to the expression "pseudo-general paralysis." He explains that the term "general paralysis" as used at present tends to cover many cases which are not truly general paralyses, but really are cases of insanity associated with a form of paralysis which, strictly speaking, is only partial. Dr. Hyslop next considers the twofold meaning of the term "general paralysis" in extension and intention, and points out the limitations enforced upon it by the addition of the words "of the insane." The only exemplification, he remarks, is in the stage immediately preceding dissolution, and this he regards as the explanation of the wonderful truism that general paralysis is invariably fatal. But he proceeds: "As it at present stands, general paralysis would appear to be best defined as a progressive disease which begins anyhow but ends somehow." The different definitions of general paralysis are next considered and their insufficiency pointed out. He regards general paralysis as a disease in which there is progressive paralysis of all mental and physical functions terminating in complete dementia on the one hand and complete paralysis on the other. Strictly speaking, it is pointed out that th

Digitized by Google

only condition answering to such a definition is death. He next explains that by the term "pseudo-general paralysis" he means to denote no particular disease, but to imply that there are certain forms of paralysis which are like general paralysis and which have been mistaken for it, but which in reality are partial paralyses, mainly cerebral with associated mental degenerations. The different forms of this pseudo-general paralysis are next alluded to. Thus alcoholic general paralysis from the symptomatic point of view is almost identical, or may be so, with true general paralysis, but the bodily and mental symptoms gradually disappear. The attacks may be repeated and ultimately such patients become alcoholic dements. Lead intoxication also gives rise to one of these pseudo forms. The chief difference is in regard to course and prognosis. The affection is an essentially curable one and has a tendency to recur under the influence of suitable conditions. Febrile diseases, such as typhoid fever &c., are occasionally followed by a condition simulating general paralysis, and so also is malaria, but in such cases the course of the disease is widely different from that in true general paralysis, and the pathology is consequently distinct. The relation of syphilis to general paralysis and the occurrence of a pseudo-general paralysis in connexion with syphilis are next alluded to and the difficulties surrounding the determination of this are fully recognised. Sunstroke he does not think an actual cause of general paralysis, but he thinks the sequelæ of sunstroke are not uncommonly mistaken for the symptoms of general paralysis. In conclusion, Dr. Hyslop submitted to the meeting two points for consideration: (1) whether the term "general paralysis" is entirely satisfactory and not merely convenient, and whether it is desirable to substitute another—e.g., progressive paralytic dementia; and (2) whether by viewing general paralysis as an entity we should be able better to avoid the danger of false prediction as to the course of the disease. The whole paper is a very interesting contribution towards the elucidation of many difficult points, and it brings out clearly the need that there is for the careful consideration of each case of supposed general paralysis on its own merits, and especially as regards antecedent conditions which may have causal connexion with the onset.

MR. REGINALD ACLAND ON THE HOSPITAL SATURDAY FUND.

THE recent address of Mr. Acland, as the chairman of this Fund, is worthy of the attention of all who are interested in the relation of the working classes to the medical profession on the one hand and to the great medical charities on the other. It is a courageous deliverance for one in Mr. Acland's official relation to the Hospital Saturday Fund. It does not hide the weak points in the administration of the Fund. It discloses faithfully a want of fervour in the council and even in the executive committee. The street collection—which we have always regarded as rather a waste of strength and which was smaller last year by £160 than the year before—Mr. Acland would give up entirely and would devote more effort to a whole-hearted attempt to place the workshop collection on a wider and more effective basis by securing, for this end, the coöperation of local committees. This collection showed last year an increase of £748. It is undoubtedly the feature of the Hospital Saturday Fund by which, as we have always maintained, it will be judged. But it is as yet far from satisfactory. The position of the working classes is improving much, and their wages more. Nobody will say that the sum of £18,000 from the workshops of London represents either the means or the obligations of the working classes to the hospitals of London, in which the highest skill and the best nursing are placed at their disposal. Mr. Acland will do well to continue, in the spirit of his able address, to urge his colleagues to assist in the development of this feature of the Fund. His remarks on the different principles on which the Hospital Sunday Fund and the Hospital Saturday Fund are distributed are worthy of consideration. We hail with pleasure the expression of his readiness as regards the Hospital Saturday Fund "to cease giving any marks at all for the attendance of Out-patients because of the enormous increase which is continually taking place in these attendances"; this increase he seeks to abate. With that object the Hospital Saturday Fund has given a fixed grant for the power of recommending patients for immediate treatment at the branches of the Metropolitan Provident Dispensary Association. We have not space to deal further with the various questions boldly dealt with by Mr. Acland. But we congratulate the Fund on having a chairman so faithful and so sound in his views of the proper functions of hospitals and dispensaries.

INFANT LIFE PROTECTION.

AT a recent meeting of the Select Committee upon the Infant Life Protection Bill Mr. A. Braxton Hicks gave important evidence. He said it was extremely difficult to prove criminal intent in connexion with deaths of nurse children, that bottle-fed children were more difficult to rear, and that foster-mothers required more supervision. In our columns for May 2nd we quoted a particularly horrible case of cruelty, and now another comes from Plymouth. A married woman who looked after three children in addition to her own was convicted of gross cruelty to two of them and sentenced to six months' hard labour. The magistrates *regretted they had not the power to order defendant to receive twenty-five lashes.* This is really excellent. We only wish the Legislature would pass a short flogging bill making it legal to flog those guilty of brutal assaults or wanton cruelty upon the bodies of (*a*) persons and (*b*) animals. Pain is the only method of appealing to some natures. Roughs of all classes and those who tear out horses' tongues, &c., would possibly think twice about their little games if they knew "the cat" would follow. But, alas! flogging is dying out, even at public schools.

LANDRY'S PARALYSIS.

IN the *American Journal of the Medical Sciences* for April Dr. Diller and Dr. Adolph Meyer relate a case which, if incomplete in some respects, is of considerable interest as furnishing an example of an obscure and not very usual condition. The patient was a married woman aged fifty-three years who was admitted to hospital on account of loss of power in the legs which had come on suddenly about ten days previously. The loss of power was not absolute, but gradually became more marked, and a week after admission she began to lose power in the arms as well, and the control of the sphincters of the bladder and rectum became impaired. By-and-bye bulbar symptoms were superadded—difficulty in phonation and deglutition—so that she had to be fed with the stomach-tube, and she died from respiratory failure about three months after the onset of the first symptoms. The psychical condition remained unimpaired until just towards the end; there was no impairment of sensation in any way, both knee-jerks were lost, and there was swelling of both knees and pain was caused in carrying out passive movements at these joints. There were no muscular wastings, no changes in electrical reaction, no fever or pain more than that mentioned in connexion with movements at the knee-joints, and no tendency to trophic disturbance. The case in its clinical features, as the writers point out, differs only from the classical picture of Landry's paralysis in the affection of the sphincters and the somewhat prolonged

Digitized by Google

course of the malady. Only the spinal cord and nerve roots were examined microscopically. In the grey matter the anterior horn cells appeared normal except that they were deeply pigmented. The white matter was changed in the crossed pyramidal tracts throughout the cord, the medullated fibres in these tracts being lessened in number and the neuroglia increased, and in one part of the dorsal region the posterior columns were similarly affected. Unfortunately the peripheral nerves were not available for examination, so that the morbid anatomy of the case remains in great part uncertain. At the conclusion of the recital of their interesting case the writers give a *résumé* of the different conditions, clinical and anatomical, which have been recognised as constituting "Landry's paralysis," and from a consideration of these they feel justified in including their case in that group.

UNIVERSITY COLLEGE HOSPITAL.

A FESTIVAL dinner in aid of University College Hospital was held in the King's Hall at the Holborn Restaurant, London, on Wednesday, May 6th, when His Royal Highness the Duke of Cambridge, K.G., presided. Replying to the toast of "The Houses of Parliament," Lord Reay took occasion to point out the advantages which would accrue to the nation if the medical profession were represented in the Upper Chamber. The toast of the evening was proposed by the Duke of Cambridge. He called attention to the alarming decrease in the income of the hospital. Whereas in 1894 the subscriptions received amounted to £2007, last year they only reached the sum of £1978, and the same decrease was noticeable in both donations and legacies. It may be, as the Duke said, that there is a tendency on the part of the benevolent to run after new institutions and leave the old ones to take care of themselves. New institutions are necessary with a growing population, but old ones, especially those which can show a record like University College Hospital, should not be neglected. At the close of last year the debt reached a total of £14,765, an increase of nearly £3000 upon the previous year. It is gratifying to note that donations amounting to £1444 were announced by Mr. Newton H. Nixon, the secretary, but a great deal more is wanted if the institution is still to carry on its beneficent work untrammelled by debt.

DEATHS UNDER ANÆSTHETICS.

A DEATH under chloroform occurred on Feb. 26th in the Royal Infirmary, Bristol. We are indebted for full notes to Mr. Maurice Barber, junior house surgeon. The patient, a lad aged fourteen, suffered from recurrent appendicitis, for which an operation was to be performed under chloroform. The patient had taken chloroform successfully in November, 1895, and on the present occasion was carefully examined before the anæsthetic was administered. About twelve minutes after the commencement of the administration and five minutes after the operation had been in progress the boy became pale. The pupils were contracted and reacted to light. Chloroform was stopped and a few minutes later the patient became blanched, the pupils dilated, while respiration grew shallow. No pulse could be felt in the facial artery. The head was drawn over the end of the table and artificial respiration and other measures for resuscitation were practised. The patient breathed at intervals for ten minutes. After this respiration almost ceased, although occasional inspiratory gasps occurred for fifteen minutes longer. Artificial respiration was kept up for over an hour. No heart sounds were to be detected. After the first partial dilatation of the pupils a semi-contraction occurred, the pupils being of unequal size, but this was followed by medium dilatation. Besides artificial respiration inversion and electrical stimulation of the heart were practised. Ether and strychnine were injected hypodermically. Chloroform was given by a medical man who has an experience of 700 cases. A Skinner's frame was used and from two and a half to three drachms were administered. The mask was held one inch and a half from the face. The necropsy showed dilatation of the right ventricle with thinning of the walls; the lungs were markedly emphysematous; and tuberculous deposits were found upon the abdominal viscera. The operation—an abdominal section—was commenced but not completed, but there does not appear to have been any unusual amount of shock attendant upon its performance. — The death of a patient under chloroform is also reported from the Cumberland Infirmary, Carlisle. The patient, a lad aged eighteen, was kicked in the thigh in February and an operation was performed under chloroform. Subsequently in April, as a further surgical proceeding was necessary, chloroform was again administered. A thorough examination of the patient was made on each occasion and no organic visceral disease was detected. When the operation was practically over the patient suddenly became very pale and died. This was twenty minutes after the first chloroform was inhaled. The account furnished to us by the house surgeon does not help to explain the sad occurrence. The death appears to have been caused by the chloroform and to have been due to syncope.— We have been favoured by Dr. Smart with careful notes of a death under chloroform which recently took place at the workhouse hospital, Toxteth. The patient, a dock labourer aged thirty-two, was upon admission much collapsed and had been suffering from intestinal obstruction for ten days. The pulse was irregular. He was admitted into the wards, and when operation was decided upon chloroform was given, although it was intended to maintain the anæsthesia when once obtained by ether. Chloroform to the extent of a drachm was given when violent struggling took place. The man suddenly sat up and then fell back dead. The necropsy showed the heart to be somewhat dilated. This case again shows the great danger to the patient of struggling. The muscular tension not only mechanically interferes with the circulation and unduly taxes the heart, but fixes the thorax and either renders respiration impossible or sorely hampers it. The quantity of chloroform given was extremely small.

SALE OF BAD MEAT.

WE have again this week to comment upon more cases of this description in which convictions have been obtained and fines inflicted. Two charges were brought against a butcher of Birmingham, one for having on his premises three carcases of veal which were unfit for food and another for having bad meat hanging in his shop. The carcases of veal were said to be black and yellow in colour and covered with slime, while the meat taken from the shop was decomposed and gave off a very bad smell. The defendant was fined £20 and costs in each case, with the alternative of two months' imprisonment. Another case, also at Birmingham, occurred, where meat which was green from mould was found hanging with healthy meat, presumably for the purpose of selling the good and the bad together. Here the defendant protested that he had not put the bad meat under the counter because of the rats which pulled it about, but the magistrates failing to see the matter in the same light, imposed a fine of £10 and costs. A third case occurred at Clerkenwell, where a dealer was fined £20 for depositing at the premises of a salesman the body of a heifer which showed traces of having suffered from pleuro-pneumonia. It is to be hoped that a series of heavy punishments will in some measure stop the sale of putrid meat, which is apparently an evil that is growing in extent and no doubt affords a substantial profit to the vendors. It is not only a business fraud in the sense that a damaged article is sold for a good one, but bad meat is liable to produce serious illnesses in those who are unfortunate enough to eat it. In the best interests of public health the most stringent means

Digitized by Google

should be used to keep such practices down. In connexion with this subject Dr. Sedgwick Saunders, the medical officer of health for the City of London, states that in 1882 the total meat supply to the Central Markets alone was 211,461 tons, whereas in 1895 it was 347,283 tons, an increase of 64 per cent. In 1882 there were 175 tons condemned, and in 1895 no fewer than 599 tons, an increase of 242 per cent., while in the first three months of this year 127 tons were seized. The inspection of the huge quantities of meat sold is far too much for the powers of the present number of inspectors, with the result that the poor are often imposed upon by the sale of inferior and unsound meat. On the recommendation of the medical officer of health the Commissioners of Sewers have determined to increase the staff of meat inspectors to six, the new officials commencing at a salary of £200 a year each.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

WE have already given an abstract of the annual report of this useful society[1] which was read at the annual meeting on May 1st, and on which the society may be congratulated. After this meeting the annual dinner of the society was held. Mr. Hutchinson, president of the society, was in the chair and was supported by various visitors, including Mr. Warburton, the counsel of the society. The dinner was the more interesting by reason of the presence of ladies. Mr. Hutchinson, in proposing "Prosperity to the Society," dwelt with feeling on the efforts of the society to bring about an honourable amalgamation, so much to be desired, with the sister society. Dr. Glover and Mr. Warburton returned thanks for the visitors. Pleasant music was discoursed and all present seemed to enjoy the entertainment. The toast of the chairman's health was proposed by Dr. Paramore and seconded by Dr. Heron.

SERUM TREATMENT OF DIPHTHERIA IN CRACOW.

DR. STAPA has presented to the Cracow Medical Society a report of the results obtained by the serum treatment of diphtheria in the Children's Hospital of that city. During the year 1895 the number of children subjected to it was 258. Of these the mortality was 22 per cent. This compares very favourably with the mortality in the ten previous years, which was as high as 56·3 per cent., there being 709 deaths out of a total of 1354 patients who were treated by other methods. Various serums were employed—Behring's, Roux's, Aronson's, Buivid's, and Paltauf's. Laryngeal croup occurred in 165 cases, and a rash having the appearance of scarlet fever and lasting from two to sixteen days in fifty-eight cases. It was noticed that certain samples of serum always produced rash. No effect on the occurrence of albuminuria by the serum could be shown. There were seven cases of return of the disease after from ten to twenty days and three cases in which it returned after an interval of from two to three months.

THE DOOM OF THE SILKWORM AND THE HORSE.

WE know that that useful beast of burden and of draught—the horse—is threatened with expulsion from our highways by the introduction of auto-cars, and now it would seem that the silkworm will soon be dispensed with as a source of silk. We wonder what law of evolution it is which just now appears to be bringing about these drastic changes and threatens to lead to the extinction of two most useful members of the animal kingdom. Silk in future is to be made from wood, and thereby a new British industry is to be installed in Lancashire which is calculated in a measure to add to the commercial prosperity of that district which has been so much menaced of late. It appears from an account contained in the *Times* of May 2nd that the process consists in nitrating wood pulp and afterwards submitting it to pneumatic pressure so that ultimately filaments are obtained of which no fewer than ten are required to make up the thickness of a single human hair. The small orifices through which the liquid matter is forced are known as "glass silkworms." After it is drawn out into filaments and passed through a process of weaving the artificial silk is denitrified and it is then rolled to produce lustre. The invention cannot fail to have an important bearing on modern life and custom, and it may not be without some influence in deciding the momentous question which was seriously discussed in our columns some years ago as to the desirability and rationality of the medical man continuing to wear a tall silk hat.

[1] THE LANCET, May 2nd, 1896.

A TERRIBLE COLLIERY DISASTER.

"OVER sixty coffins have been ordered by the colliery company" is the gruesome announcement made in an account of the colliery explosion near Leeds in the daily papers of Monday last week, and probably the actual number of lives lost was more than sixty. The harrowing details of the disaster need not here be recounted—suffice it to add that the explosion appears to have been one of terrific and exceptional force. Yet we learn that the mine was considered so safe that it was worked with naked lights and that gas was practically unknown in the workings. The cause of the explosion is, therefore, surrounded with considerable mystery. We do not know, however, and we can gather no information as to whether the mine was dry and dusty, and if so whether the precaution of damping was taken. Then, again, there is no evidence as to whether some high explosive or gunpowder was in use for shot-firing purposes. Evidence on this latter point is of special importance since the use of high explosives in the place of gunpowder greatly limits the risk of explosion in dry, dusty, and fiery mines. We trust that the colliery owners will be able to satisfy the Home Office on each and all of these points. It is a significant fact that on the very day of the disastrous explosion a colliery warning was issued directing the attention of miners to the change which had taken place in the atmospheric conditions over the British coal fields and "during Wednesday night an anti-cyclone of considerable size and intensity began to affect the coal country, the barometer rising more or less decidedly everywhere." Is any heed paid to these colliery warnings?

LONDON POST-GRADUATE COURSE.

THE opportunities afforded by the London Post-graduate Course have been, as our readers know, largely used by members of the profession desirous of acquiring a practical knowledge of the more recent advances in medical science, and the programme now unfolded for the coming season promises well. Instruction will be given at the following hospitals and institutions:—The Royal London Ophthalmic Hospital, Moorfields (diseases of the eye); the Hospital for Diseases of the Skin, Blackfriars (skin diseases); Bethlem Royal Hospital for Lunatics (mental diseases); the London Throat Hospital, Great Portland-street (diseases of the throat, nose, and ear); the Bacteriological Laboratory, King's College (pathogenic organisms); the Central London Sick Asylum, Cleveland-street (clinical lectures); the Parkes Museum, Margaret-street (lectures and demonstrations in hygiene); and the British Institute of Preventive Medicine, Great Russell-street (chemistry and bacteriology of urine). The teaching will be, as far as possible, of a practical character, including demonstrations of selected cases and lectures on

Digitized by Google

the diagnosis and treatment of disease. There will also be instruction in the use of the microscope, ophthalmoscope, laryngoscope, and aural and nasal specula. The hours of attendance are all in the afternoon, at various times, from one o'clock to eight. The summer term extends from May 4th to June 29th, and the winter term from Oct. 5th to Nov. 27th. The fees for attendance at any single course are £1 1*s*., £2 2*s*., or £3 3*s*., according to the number of lectures and demonstrations. Inquiries and applications for cards of admission should be addressed to the secretary, Dr. J. Fletcher Little, 32, Harley-street, W.

MEDICAL CERTIFICATES AND THE LONDON SCHOOL BOARD.

ON Wednesday last Dr. Glover, Dr. Bridgwater, and Dr. Colcott Fox had an interview of some length with the Attendance Committee of the London School Board with a view to the removal of the friction which unhappily prevails between the profession and the Board in reference to medical certificates. The deputation was most courteously received by the members of the committee, who showed a desire to meet as far as possible the wishes of the profession. They will announce in a few days how far they can do so.

THE May dinner and annual meeting of the Aberdeen University Club (London) will be held at the Holborn Restaurant on Wednesday, May 20th, at 7 P.M. Dr. Nicolson, one of the Lord Chancellor's Visitors in Lunacy and late Superintendent of Broadmoor Asylum, will take the chair, and we are certain will adequately discharge the duties. It is hoped that he will be supported by a large gathering. Members wishing to attend are requested to communicate with the hon. secretaries, Mr. J. Gerald Laing, 2, Brick-court, Temple; and Dr. James Galloway, 21, Queen Anne-street, W.

AMONG the fifteen candidates whose names are announced as having been selected by the Council of the Royal Society for recommendation for election into the society are two members of the medical profession—Dr. F. W. Mott, Assistant Physician to Charing-cross Hospital, and Mr. Charles Stewart, Professor of Comparative Anatomy and Physiology and Conservator of the Museum of the Royal College of Surgeons of England.

A GENERAL monthly meeting of the members of the Royal Institution was held on the 4th inst., Sir James Crichton Browne, M.D., F.R.S., Treasurer and Vice-President, presiding. The following medical men were elected members:—Mr. J. H. Badcock, M.R.C.S. Eng., Dr. W. J. Gow, and Dr. Thomas Oliver, F.R.C.P. Lond.

DR. F. J. WALDO, medical officer of health to the Middle and Inner Temples, has been called to the Bar. On the same day Dr. William M. Leslie and Dr. Sidney R. Dyer were called to the Bar.

MR. A. A. KANTHACK, M.D. Lond., has been approved as Deputy for Dr. Roy, the Professor of Pathology in the University of Cambridge, for a period of three months at a stipend of £120.

WE understand that Sir William Roberts, M.D., F.R.S., has been appointed to succeed Dr. Wilks as representative of the University of London in the General Medical Council.

THE annual dinner of the West London Medico-Chirurgical Society will be held at the Café Monico, Piccadilly-circus, on Wednesday, May 20th, at 7.30 P.M.

Pressure on our space has compelled us to omit the usual weekly instalment of the biography of THOMAS WAKLEY, *the Founder of* THE LANCET.

THE NILE EXPEDITION.

SINCE our last report intelligence has been received of a cavalry action at Akasheh—the first fight of the campaign. Some squadrons of Egyptian cavalry attacked, about four miles from Akasheh, a mixed force of Dervish horse and foot numbering altogether between 1200 and 1300. The Dervishes were completely defeated and made so hasty a retreat that the Soudanese infantry battalion supporting the Egyptian cavalry had not an opportunity of taking part in the encounter. The Egyptians behaved uncommonly well, having charged the Dervishes with pluck and determination, showing that their previous military preparation and training had not been thrown away and that under the leadership of English officers they were capable of giving a very different account of themselves to what they had done on most previous occasions. The heat during the action is described as having been terribly trying to the troops. The thermometer registered 116° F. in the shade, and in the open desert, owing to the radiation from the sand and rocks, it is stated that the temperature reached 150°. The special correspondent of the *Standard* gives some illustrations of the drying effects of the heat on all sorts of stores at Wady Halfa in causing their shrinkage, amounting in some cases to 20 per cent. Onions lost a thousand pounds out of five thousand; meat slaughtered at seven in the morning and packed in wet cloths lost 15 per cent. by seven the next morning and became unfit for food. The baking of bread is a great difficulty; native bakers have taken over this work for the troops in consequence of the men with the force being unable to stand it for more than a short time. Considering the intolerable heat the health of the expeditionary force and the energy and activity that are being displayed at all the stations on the Nile are remarkable.

There appears to be ample accommodation for the troops at Wady Halfa and elsewhere. Time is an essential element in making proper arrangements, and the comparative inactivity of the Dervishes up to the present has enabled the military authorities to make their preparations. The more rapid a campaign the greater is the strain, of course, upon all departments. According to all the reports that have been received in this country the amount of hospital accommodation provided for the troops is ample and the arrangements satisfactory. With the exceptional heat that prevails (tempered happily by a breeze as a rule), the sand-storms, the toughness of the meat, and the monotony of the diet, it is only to be expected that there will be a good deal of sickness. The heat at Wady Halfa is very great and is likely to continue to be so for some time. There has already been a death from heat apoplexy; still the troops are so far bearing the effects of the climate better than might have been anticipated. The excitement and novelty of the scene, the work in which they are engaged, and the success that has hitherto attended their labours have all tended to keep them in excellent spirits. The telegraph to Akasheh is completed and in operation, and the railway is progressing, but the work has proved rather more tardy and difficult than was anticipated. The Camel Corps is stated to be now amply provided with camels, and according to the latest accounts the wounded at the late fight are doing well. Every effort is being made, we are glad to say, by the erection of ice-making machinery to provide the troops with ice as far as possible.

LITERARY INTELLIGENCE.—A new work on Descriptive and Practical Histology has been written for the use of students by Mr. Arthur Clarkson, M.B. Edin., formerly demonstrator of physiology in Owens College, Manchester, and in the Yorkshire College, Leeds. The publishers will be Messrs. John Wright and Co., Bristol, and Messrs. Simpkin, Marshall, Hamilton, Kent, and Co., London. It will consist of about 600 pages with 174 coloured original illustrations, and will be divided into seventeen chapters in which the student will be taken tutorially over the various parts of the subject and instructed in the methods of preparation.

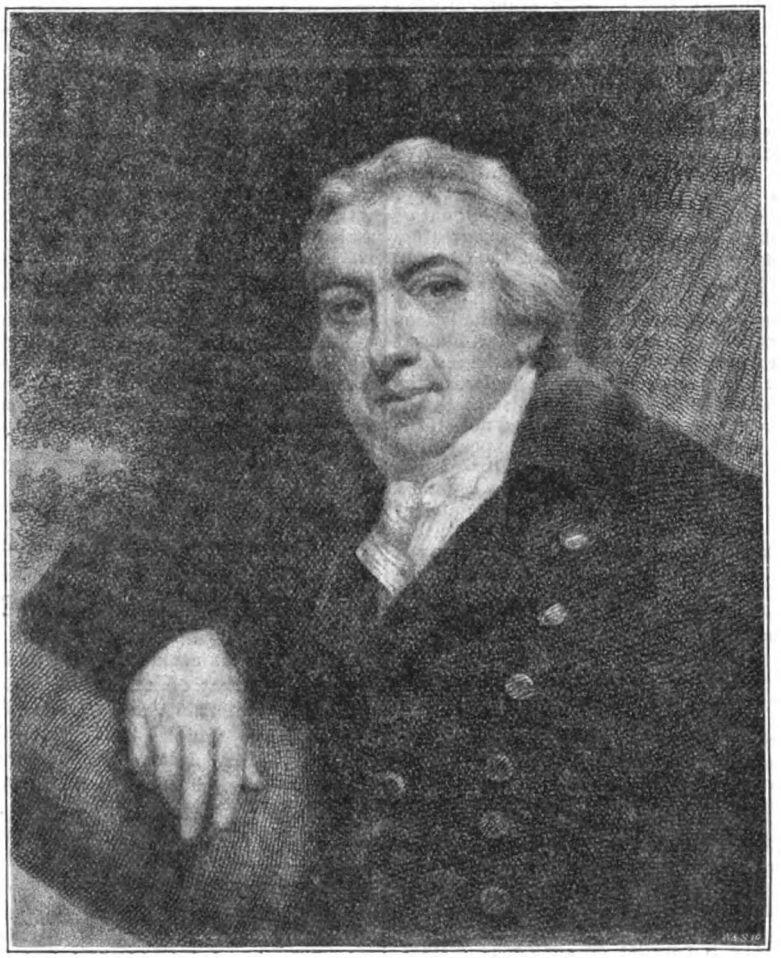
JENNER AND HIS WORK.

IN a recent *brochure* by a prominent anti-vaccinationist it is seriously suggested that one reason for giving up vaccination is that, as regards its prevalence, small-pox is now a very inconsiderable disease and contributes a mere fraction to the total death-rate of this country. In advancing this argument the anti-vaccinationist in a single sentence shows how illogical even a well-educated anti-vaccinationist can be, and at the same time in stating the fact on which the suggestion is based he pays an unwitting compliment to the author of vaccination. It is unquestionably true that small-pox in the end of the nineteenth century contrasted with small-pox as it was in Jenner's time has diminished from the proportions of a giant to those of a dwarf, and for this diminution it is not possible to find any explanation other than vaccination which will meet all the facts of the case. If it be suggested that the diminution in small-pox was owing to the cessation of the practice of variolous inoculation, the reply is not far to seek. It is not at all certain that artificial variolation did increase the total amount of "natural" small-pox in the country. It is possible indeed to argue for quite the opposite view, and many competent observers, who were well acquainted with the influence of small-pox inoculation both in large cities and in rural districts, had no doubt whatever, judging from their own knowledge of local facts, that the practice had greatly diminished the total mortality from the disease. In places, too, where variolation had never been more than an experiment but where small-pox largely prevailed the introduction of vaccination was followed by the same kind of diminution in small-pox that occurred in other places where the spread of vaccination was coincident with the shrinking of the older practice of variolation. If it be alleged that it is to sanitation and not to vaccination that we owe the fall in small-pox, the reply is manifold. Sanitation cannot account for the fact that whereas before the introduction of vaccination in a given community four children died of small-pox in the first half year of life for every one child that died of it in the second half year of life, but that when in this community vaccination was made compulsory at the age of six months the proportion of deaths in the second six months of life fell so amazingly that instead of being four times greater than for the first six months it became four times smaller. Sanitation cannot account for the fact that in the last century small-pox was a disease of childhood, but that when vaccination came into vogue the pestilence at once ceased to prevail among the vaccinated children, while later, after these children had become adults, it began to reassert some part of its sway among them. Sanitation cannot account for the fact that in places where there was no sanitation the introduction of vaccination was followed by the usual striking diminution in the prevalence of small-pox. Sanitation cannot account for the fact that in hospitals at a time when the only protection which nurses attending to sufferers from typhus fever had against typhus fever consisted in a previous attack of the disease, and when the only protection that probationers in typhus fever wards could hope for was a non-fatal attack of that fever—that at this time their sister nurses in the small-pox wards, living and breathing in an atmosphere saturated with the poison, remained free from attacks of small-pox, though, indeed, an attack of typhus fever was not unknown amongst them. Nor can sanitation account for the fact that among small-pox nurses of the present time the many who are revaccinated remain free from danger while the few who by some mischance escape revaccination are forthwith attacked by small-pox, nor for the fact that in the small-pox wards at Leicester, where anti-vaccination was so popular a cult that some half-dozen of the nursing staff refused revaccination, all but one of the half-dozen were attacked by small-pox and one had to pay the death penalty for her temerity; while of the sixteen or thereabouts who submitted to revaccination not one had also to submit to small-pox.



EDWARD JENNER, M.D., F.R.S.

(From a painting by J. R. Smith, R.A.)

It is in very truth to Jenner and to vaccination that the nineteenth century owes its freedom from small-pox. In the present day we can have little appreciation of the difficulties with which he had to contend before he could present to the world his new system of small-pox prevention. He was a busy practitioner in a wide rural district, subject to all the distractions of general practice and of social duties, and with his scanty leisure broken in upon and interfered

Digitized by Google

with by the sudden calls to which every country doctor is liable. He was quite unprovided with the laboratories and with all the apparatus that make exact research so possible and even so convenient in our own time. Even half a century later so able and persevering an observer as Robert Ceely, with the way already paved for him by Jenner and other less distinguished workers, found enormous difficulties in his researches, carried on amidst the filth and darkness of country cowhouses. For Jenner, however, there was little or no assistance to be obtained from anything that had gone before. Other practitioners besides himself had seen good reason to believe in the traditions of the dairies, but none of them had ever ventured seriously to grapple with the subject as one that could be made generally useful in the interests of mankind. In these days the term cow-pox was popularly used to mean anything and everything in the way of eruption, or excoriation, or abrasion, or fissure, that could attack the teats and udders of cows. Even after Jenner had satisfied himself that all cow eruptions were not cow-pox, and that it was cow-pox and cow-pox alone which had the peculiar anti-variolous power, and after he had published his "Inquiry," we find a veterinary surgeon, apparently of good standing, describing in print as cow-pox a teat affection which obviously was not cow-pox and which, correctly enough, the veterinary surgeon opined to have no power against small-pox. We have further to recollect that Jenner had, to begin with, no knowledge of the various operative details which we, in the present day, know to be absolutely essential to the proper carrying out of vaccination. From the cow's teats there was the greatest possible risk of taking along with the lymph of the cow-pox itself all manner of extraneous matter, the result of filth in the lairs, of dirt on the milker's hands, and of what Ceely long afterwards described as "the merciless manipulations of the milkers." So, too, he had to decide for himself whether matter either from the cow's teats or from the vesicles of a vaccinated arm should be used in the vesicular, or the pustular, or the ulcerative stage. Before him also there was the fact that his experiments had to be conducted not on the lower animals, but on human beings, and that the possibility of mishap made very weighty the responsibility of the operator. With such material as Jenner had to begin by using it is not surprising that at first he called the inflammation surrounding the vaccine vesicle "erysipelatous" rather than erythematous, and that he gave careful instructions as to the prevention and treatment of possible ulceration following local disease. His theory that cow-pox itself had its origin in an equine disease led to considerable doubt and difficulty among some of his *confrères*. Here, too, there was a popular and all-embracing name "horse-grease" to be contended with, and, as in the case of the bovine disease so with the equine, it was only one particular malady among several that went under the same name that had anything to do with cow-pox or small-pox. One result was that in London endeavours were made to produce cow-pox by inoculating material from some unhealthy or erysipalatous condition of the heels of a horse and that the failure of these attempts led to doubt as to the very genesis of the Jennerian system. Two or three years later, however, Loy of Whitby published his observations, which went to show that Jenner's fault was rather in the use of the name than in the reality and in the supposition that horse-pox was necessarily the parent of cow-pox rather than merely a parallel or analogous disease. It is not easy in these days to realise the fact that when vaccination began to be practised in London any weight could be attached to the opinion of John Birch of St. Thomas's Hospital who held that "small-pox was a merciful provision on the part of Providence to lessen the burthen of a poor man's family," or of Dr. Rowley who declared that "the small-pox is a visitation from God; but the cow-pox is produced by presumptuous man: the former was what heaven ordained, the latter is perhaps a daring violation of our holy religion." Nor can we read without a smile the record of that famous consultation between Rowley and Moseley, regarding which Rowley reports: "Dr. Moseley ..... saw this case of the ox-faced boy by my desire. He observed to me that the boy's face seemed in a state of transforming and assuming the visage of a cow." Yet 100 years ago all these assaults on vaccination had their own weight. The proposal to introduce by way of inoculation into the human frame any matter from the body of a lower animal was entirely new. The cow-pox itself, moreover, especially in its differences from the yellow-pock and the blister-pock or white-pock and the other diseases with which it had been confused, was quite unknown to the profession at large. Jenner's "golden rule," so early and so clearly formulated by himself and so important for safe and successful vaccination, to take matter from a vesicle only when it is clear and limpid before it has reached the pustular stage and before the surrounding areola has begun to appear, was openly scouted by at least one of the principal vaccinators in London. Through all these difficulties and through many others which it would take too long to detail here Jenner had to fight his way. Sometimes he was inclined to despair, but his absolute certainty and knowledge of the value of vaccination spurred him on to continued endeavour, and his strong and sagacious grasp of every essential principle of the practice enabled him to deal with every fresh objection as it arose and with every fresh blunder as it was perpetrated. It was not given to Jenner to know all that we now know about vaccination. He hardly lived long enough to enable him to appreciate the need for re-vaccination. It was years after his death, when the children vaccinated in the early years had grown to be adults, before that essential came to be fairly recognised. Similarly in the early years experience as to the importance of sufficiency of amount of the local disease had not accumulated, and it was left to another generation to formulate the rule that the best results of vaccination can only be obtained by operating both efficiently and sufficiently. But in all other respects Jenner's knowledge of the essentials of vaccination was remarkably thorough, and in our own day little has been added to it. It has fallen to the lot of no other single member of the medical profession, or perhaps even of the human race, to be the direct means of saving so many lives, so much disfigurement, and so much concurrent grief and misery. The thanks of the world are due to-day to the quietly thinking and quietly working village practitioner in Gloucestershire, and, to quote the words of Sir John Simon, "the close of the eighteenth century, which had much to darken it, will be remembered to the end of human history for the greatest physical good ever yet given by science to the world."

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1894.

[FIRST NOTICE.]

AMONG the numerous official reports rendered to different Governments that of the Sanitary Commissioner with the Government of India occupies—and in our opinion very deservedly so—a high place. The voluminous character of the Sanitary Commissioner's reports, the number of statistical tables, and the amount, as well as the variety, of material they contain are, no doubt, sources of difficulty and embarrassment to the reader; but it must be borne in mind that the facts and figures connected with the vast populations with which they deal may without hyperbole be termed colossal. The text of the report itself is nevertheless, and apart altogether from the tables and details required for official reference, always valuable and instructive, and the present volume strikes us as a very able one. It contains an amount of information, with an analysis of the results of recent researches and theories of disease, not to be met with elsewhere. A note at the commencement of the volume indicates that these annual reports will probably undergo some modification in future, for it states that the recommendations of the Army Sanitary Commission as to altering and reducing the number of the tables were received too late to be acted upon in the case of the present report.

In the case of so vast a country as India, with its imperfect systems of registration and with the large amount of disease that either escapes observation altogether or at least is subjected to no scientific observation, it may be urged that the record of figures and alleged facts is quite valueless and the labour in collecting them simply a waste of energy. But such is certainly not altogether the case, for we possess in our army and in our gaol populations scattered over different parts of India accurate and reliable tests and gauges of the medical events of any given year. The European

Digitized by Google

army in India and the native army of that country, though to a less extent, together with the inhabitants of the gaols, amount in the aggregate to a very large population living under conditions that are well known and under skilled medical surveillance. Moreover, as regards the epidemic and endemic diseases of India, these are commonly attended with some familiar features or phenomena that cannot altogether escape the notice of the least observant and usually declare their presence also by an increased mortality; and data gleaned from native races can therefore be compared with, and corrected by, those afforded by the military and gaol communities with a similar environment and living in their midst.

The urban and rural registration of births and deaths, if very far indeed from perfect as regards the native population, is still not altogether illusory and it is improving year by year, and the presence of an unusual amount of disease is soon bound to declare itself and be recorded. While we have but little sympathy with those who are content to point to what has been already done in India and to oppose further progress as if we had reached a stage of finality we have, if anything, still less sympathy with those self-satisfied, irresponsible people who make the East a touring ground for the cold weather and regard everything which differs from the Western standard of civilisation as wrong and requiring to be radically and promptly changed, regardless of the traditionary customs and feelings of the people, political expediency, and financial considerations. But to come to the subject of the report itself. Section I. deals with the meteorology of the year and gives a summary of the meteorological phenomena month by month. Section II. treats of the European army in India, and it contains much that merits and should receive grave attention. The year 1894 was a wet and unhealthy one, and the number constantly sick per 1000 was unusually high. Venereal diseases caused 34 per cent. of the total sickness and ague 27 per cent.; and of the total deaths enteric fever caused 36 and cholera 13 per cent. The total death-rate in 1893 was only 12·61, whereas in 1894 it was 16·07 per 1000 of strength. The following table gives the percentages respectively of enteric fever, hepatitis, dysentery, and pneumonia in the total deaths of each presidency in 1894.

—	Bengal.	Madras.	Bombay.
Enteric fever	36·5	30·7	36·1
Hepatitis and hepatic abscess	6·6	10·2	10·8
Dysentery	3·9	5·5	2·1
Pneumonia	5·4	3·9	2·1

The prevalence, and unfortunately increasing prevalence, of venereal diseases in the European army of India constitutes a most serious cause of inefficiency, and it is not easy to exaggerate the magnitude of the evil from whatever point of view it is regarded. The immediate effects of venereal disease are to render, we are told, 3062 men daily ineffective; but it is impossible to say how many of these men become affected with secondary syphilis. The returns only show the admissions into hospital, and one case may, of course, represent several admissions. A table at p. 43 of the report, prepared by Brigade-Surgeon-Lieutenant-Colonel Exham, and placed at the disposal of the Sanitary Commissioner by the Principal Medical Officer of Her Majesty's Forces in India, brings out the actual condition of the army as regards venereal disease in a very forcible way. It reveals the fact that of the 70,642 British soldiers present in India in July, 1894, only 37 per cent. had never suffered from venereal disease, while 63 per cent. had at some period of their service contracted it in one form or other. The ratio of admissions for these diseases in the army of India—511·4 per 1000 in 1894—is vastly higher than that of most of the Continental armies and higher than the ratios of our troops in other British possessions. There are no means of comparing the figures with those relating to the civil adult male population; but, judging from the results of inquiries by Mr. Acton in the surgical divisions of our larger hospitals in London, there is reason for believing that the disease is far more prevalent than is generally believed.

As regards the European military population of India a return to a system of long service and increased facilities for marriage seems impracticable, and the influence of moral and physical efforts—such as increased cleanliness and athletic amusements—is inadequate to cope with the evil. That the compulsory lock hospital system in India, notwithstanding all the difficulties and defects that attended its working, nevertheless did much good cannot, we think, be doubted; but public opinion and the House of Commons will not apparently tolerate new and more stringent legislation in this direction, and it is, moreover, alleged that the experience of the cantonment lock hospital system in India failed to effect that amount of reduction in the prevalence of these diseases which its advocates hoped for or the cost incurred warranted the Government in expecting. A system of voluntary lock hospitals in India on the one hand, and the provision of healthy occupations and recreations for the soldier on the other, have, however, proved inoperative. The question comes, and comes with pressing force, What is to be done? The powers of the military and police authorities to exercise a greater surveillance over illicit prostitution may be enlarged, and various things may be done no doubt in this and similar directions, but we can scarcely believe that these will form an effectual remedy. The authorities in India should certainly have the power of compelling diseased women to submit to treatment in hospital or to leave the cantonment. They would do so in the case of any other infectious disease, why not in this? A woman under such circumstances is surely an acknowledged source of danger, and of very grave danger to all who may consort with her. If the evil continues, as we fear it will, the only practical method of coping with it, as it seems to us, is by the re-establishment of a compulsory lock hospital system and by legislative enactment of some kind, carried out and applied even more systematically and stringently than before.

Some method could surely be devised by which these unfortunate women could, with every regard to humanity and considerate kindness, be treated and be prevented from spreading infectious diseases among our troops. We recognise the difficulties, but do not believe them to be insurmountable; in any case the duty of striving to limit the spread of these contagious diseases by any means in our power seems clear, and we cannot go on shirking it for ever.

We hope in our next article to deal with various other points, and especially with the summary analyses of the different views and theories at present held in regard to some of the more prevalent diseases endemic to India which are set forth in the report under review.

ANNUAL REPORT FOR 1894 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

II.[1]

WE now come to the consideration of that part of Mr. Shirley Murphy's report which treats of the influence of school attendance on the diffusion of infectious diseases. The general question of measles fatality in London has already been discussed in our notice of the Registrar-General's annual summary for 1894. It is evident, however, from the report now before us that in many London districts measles prevalence has seriously affected the regularity of school attendance, and consequently has caused much anxiety to the county medical officer and his staff. It will be remembered that in 1892 compulsory notification of measles throughout London had been suggested to the County Council by the London School Board; the former authority, however, appear to have been unwilling to incur the responsibility of so heavy an expenditure pending completion of the inquiry which the Local Government Board had undertaken with a view of determining the value of notification as a means of controlling the spread of measles in urban communities. It is surprising, however, to what extent the attendance, more especially in the infants' department of elementary schools, is reduced during an epidemic of measles. In one large school cited by Mr. Murphy the absentees from school were on one occasion 50 per cent. of the average number on the roll. Not all the children, however, were absent on account of being themselves the subjects of measles; some of them

[1] No. I. appeared in THE LANCET of May 2nd.

Digitized by Google

were kept from school because of the infected state of their homes. The notified attacks by scarlet fever were only half as numerous in 1894 as they had been in the year previous: they corresponded to an attack rate of 4·2 per 1000 of the population, against a rate of 8·6 in 1893. The case mortality, however, in 1894 was 5·2 per cent., or 0·9 per cent. higher than in the preceding year. As regards the incidence of scarlet fever on persons of different ages, the experience of 1894 accords with that of the preceding year in showing that the greatest incidence was upon children between four and five years of age. Concerning the influence of school attendance on the prevalence of scarlet fever Mr. Murphy says that the year 1894 was characterised by irregularity in the behaviour of this disease and especially by the entire absence of the usual rise in the latter part of the year. There was a decrease in the number of cases reported in the four weeks of "holiday influence" (the thirty-second to the thirty-fifth week), and the decrease was most observable among children of school ages (from three to thirteen years). Again, whilst in the four weeks following "holiday influence" there was a decrease both among infants under three and among persons over thirteen years of age, the number of attacks among children of school age increased by 33½ per cent. These facts accord with the hypothesis that the interruption of school operations was responsible for some part of the decrease in the period of holiday influence of attacks at school ages, and that the increase of attacks amongst school children in the subsequent four week period was largely due to the reopening of the schools. Mr. Shirley Murphy is convinced of the correctness of his hypothesis by the experience of the four years 1891–94. The records of the last-mentioned year furnish evidence of the occurrence of subsequent cases of scarlet fever shortly after the return from hospital of antecedent cases. In one district 24 instances of this misfortune are reported to have occurred in this year alone.

With reference to diphtheria prevalence in London Mr. Shirley Murphy reminds us that the notification statistics of the year 1893 showed that when school operations were suspended by the summer holidays there was a *notable diminution* in the prevalence of diphtheria, especially among children at school ages, and, further, that a *marked increase* followed the reassembling of children after the holidays. Precisely the same facts are revealed by the diphtheria notifications in 1894. A table in the report shows that, as had been the case in the previous year also, there was a considerable *falling off* in the notifications at school age during the four weeks of holiday influence and an even greater *rise* in the ensuing four weeks. Mr. Murphy further remarks that the August depression of the diphtheria curve in his diagram showing attacks under three years occurs somewhat later than the depression in the school age curve in a way to suggest that children under three had been infected by their older brothers or sisters, and that the decrease in the frequency of attack amongst the former was due to diminished opportunity of infection from the latter. This behaviour of diphtheria had also been noted in the year 1893. In regard, therefore, to the influence of school attendance on the spread of diphtheria as well as of scarlet fever the experience of 1894 teaches the same lesson that the preceding year had taught, and in commenting on this circumstance Mr. Shirley Murphy pertinently remarks that the attention of medical officers of health and of school authorities should be directed to the perfecting of measures for counteracting as completely as possible the tendency of the aggregation of children in school to spread infection.

The incidence of enteric fever in 1894 was somewhat lighter than in the year previous. There was, however, a notable increase in the number of attacks in the forty-ninth, fiftieth, and fifty-first weeks. This distribution of attacks in 1894 was exceptional and inquiry showed that the abnormal increase was not due to special local prevalence, but was manifested over a large area of London. It was observable in the populations supplied by all the water companies except the East London and Kent Companies. Chemical investigation showed that an intimate relation existed in these weeks between the condition of the waters supplied for drinking purposes and the condition as to flood of the rivers from which these waters were derived. Certain notable floods in November materially altered the condition of the drinking-water at a time when some new factor probably came into operation which led to increased prevalence of enteric fever in London. Mr. Shirley Murphy thinks that this increase may be best explained on the hypothesis of water-borne contagion. In an instructive memorandum on this subject he shows that whereas in the four-year period 1890–93 there had been a decrease in the number of cases notified in the forty-ninth, fiftieth, and fifty-first weeks, in the same weeks of 1894 there were, contrarily, an increase. Regretting the fact that the statistics of only a few years can be placed under contribution in order to determine what is the normal behaviour of enteric fever in London, Mr. Murphy observes that "an *increased* relative *prevalence* of enteric fever *over a very wide area* at a time when enteric fever might be expected to *decrease* raises questions whether or not the disease has been disseminated by water. All the usual modes of diffusion of infection—contaminated milk, insanitary conditions, &c.—are discussed in this memorandum, and are dismissed as inadequate for the production of an abnormal disease prevalance of such wide distribution as that which actually took place, and the conclusion arrived at is that the hypothesis of water-borne contagion affords better explanation of the increase in question than any other which has been suggested. These considerations appear to Mr. Murphy to indicate the need for watchfulness over the distribution of enteric fever in London in relation to its water-supply. The investigation of the causes leading to unequal distribution of phthisis in London districts has recently been greatly facilitated by the action of the General Register Office, which now publishes in its quarterly and annual reports the true death-rates of the sanitary areas from this disease, the deaths occurring in hospitals, workhouses, and lunatic asylums having been referred to the localities from which the patients originally came. Accordingly, Mr. Murphy has availed himself of the Registrar-General's figures to construct a chart which exhibits graphically and by means of appropriate shading the distribution of mortality from phthisis in the year 1894. Examination of the chart shows that the areas with highest mortalities from phthisis are mainly the low-lying spots near the river, which are equally notorious for heavy mortality from causes other than this. The phthisis mortality for London averages 1·7 per 1000 living, but it varies greatly in the several districts. It does not exceed 9 in 10,000 in the high grounds of Hampstead, and averages 11 in four other districts, whilst it ranges upwards to 29 in St. Saviour Southwark, 31 in Hackney, and 32 in the sanitary district of the Strand. Mr. Murphy further shows the relation subsisting between "overcrowding" and phthisis fatality. From the census returns the proportion is ascertained of the population occupying tenements of one, two, or more rooms and in which there are more than two persons in each room. Employing the term "overcrowding" to represent such usage and grouping the various districts according to the overcrowding therein existing, it is shown that the phthisis mortality in these groups increases with the overcrowding. Thus we find that in districts where the proportion of population living two or more in a room does not exceed 10 per cent. the phthisis mortality is relatively low (10·7 per 10,000), whilst in districts where the proportion exceeds 35 per cent. phthisis kills at the rate of 24·6 per 10,000 of the population. It is also found that the mortality from causes other than phthisis increases with overcrowding in like manner.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia of the Royal College of Physicians of London was held at the College, Pall Mall East, on the 30th ult., Dr. SAMUEL WILKS, the President, being in the chair.

Various formal communications were read from the Royal College of Surgeons of England.

The Rev. Thomas Bramley, husband of the daughter of the late Dr. James Copland, wrote offering for the acceptance of the Royal College of Physicians of London a portrait in oils by Room of Dr. Copland. A vote of thanks was passed on the suggestion of the President, who gave some personal details of his acquaintance with Dr. Copland as the writer of the well-known Dictionary of Medicine and as a President of the Pathological Society. Dr. Bagshawe offered to the Council a collection of engraved portraits and autographs of surgeons and men of

Digitized by Google

science formed by the late Dr. Greenhill, and this was also accepted with thanks.

A letter from the headmaster of Bury St. Edmund's school asking for a copy of the engraving of Sir Thomas Watson, to be added to the collection of worthies who were educated there, was read and the request was agreed to.

Dr. Lauder Brunton and Dr. Saundby resigned their respective examinerships.

Mr. Sinclair Gillies, M.B. Lond., of St. Bartholomew's Hospital, on the report of the examiners, was awarded the Murchison Scholarship with special commendation.

The following Members were elected as Fellows:—John Anderson, C.I.E., M.D. St. And.; Sir Hugh Reeve Beevor, Bart., M.D. Lond.; Harry Campbell, M.D. Lond.; Charles Montague Chadwick, M.D. Oxon. (Leeds); John Michell Clarke, M.D. Camb. (Clifton, Bristol); Arthur Gamgee, M.D. Edin. (Lausanne, Switzerland); William Hunter, M.D. Edin.; Arthur Pearson Luff, M.D. Lond.; Ernest Septimus Reynolds, M.D. Lond. (Manchester); and William Aldren Turner, M.D. Edin.

The following gentlemen having passed the required examination were admitted as Members:—Arnold Francis Bill, M.B. Oxon., Robert Henry Cole, M.D. Lond., Charles Arthur Mercier, M.B. Lond., F.R.C.S. Eng., Thomas George Stevens, M.D. Lond., F.R.C.S. Eng., and Arthur John Whiting, M.D. Edin. Licences were granted to a large number of candidates.

The quarterly report of the Finance Committee and the reports of the Committee of Management and of the Laboratories' Committee were read. The statistics of the examinations for the Licence and the list of books presented to the library during the past quarter were also placed before the Comitia.

THE HISTORY, METHODS, HINDRANCES, EXPENDITURE, AND POLICY OF THE CIVIL RIGHTS DEFENCE COMMITTEE.

(Continued from p. 1159.)

HINDRANCES.

IN prosecuting their labours on behalf of Mr. Anderson, and the important rights both of British subjects generally and of the members of the medical profession in particular which are involved in the case, the Civil Rights Defence Committee has had to contend with several obstacles, some of which have not yet been fully overcome. During the earlier stages of the work of the Committee there had been much misapprehension on the subject of "maintenance," or the offence of illegally contributing to carry on, or promote, actions at law without being connected with, or having any real interest in, such actions or their results. To avoid any such question the Committee undertook the case of Mr. Anderson, obtaining special leave to appeal to the Privy Council to provide funds for the other side as well, and to this Mr. Anderson gladly consented. The ideas and difficulties as to maintenance have now entirely disappeared, it being fully realised that every man, woman, and child in the Empire has an interest in, and a right to unite in defending, the rights and liberties of all British subjects. It has been already mentioned that Lord Stamford's letter giving a *précis* of Mr. Anderson's case and strongly appealing to the public for support was sent to 250 leading newspapers in London and the provinces, but that, with the exception of a brief abstract in the *Times* and short notices in a few other papers, it did not receive insertion or comment. It will, therefore, be seen how difficult it is for the Committee to avail themselves of the services of the public press for applying to the community for the funds necessary to prosecute the appeals to the Privy Council and to the House of Lords. The medical journals are staunch supporters of Mr. Anderson, and two or three well-known lay London journals, like *Truth*, the *Pall Mall Gazette*, and the *St. James's Gazette*, and a few provincial and Colonial papers have rendered substantial aid, but what is wanted is a general awakening of the public press.

Even in the ranks of the medical profession there is a certain reluctance in some quarters to uphold the rights of medical men in regard to their liberty of action to make stipulations as to fees, to decline attendance, and to retire from attendance of patients under particular circumstances where no injury is thereby inflicted—rights which are impugned by the still unquashed decisions of the Court in Trinidad in the case of Mr. Anderson. For instance, a medical practitioner whom the Committee endeavoured to influence in defence of these rights dissented from the principles above mentioned and generally accepted in the profession, considering it contrary to the duty of a medical man to make any stipulation before rendering his services as it seemed to be taking an unfair advantage similar, as he expressed it, to "holding a pistol to a man's head." Then, again, there has been considerable disinclination displayed on the part of medical corporations and bodies concerned with professional interests to take up Mr. Anderson's case by sending representatives to the Civil Rights Defence Committee and rendering pecuniary aid. In London the only corporation represented on the Committee is the Royal College of Surgeons of England, an obligation which the Council could not well escape in face of Section XV. of the By-laws, which expressly stipulates that "The Council will at all times protect and defend every Fellow and Member of the College who may be disturbed in the exercise and enjoyment of the rights, privileges, exemptions, and immunities acquired by him as a Fellow and Member or Member thereof." It is worthy of note that the solicitor of the College was of opinion that Mr. Anderson's case did not come under the meaning or operation of the by-law, but the common sense and good feeling of the Council rose superior to legal subtleties. The representation on the Committee of the Council of the Royal College of Surgeons of England is a tower of strength to Mr. Anderson, but, on the other hand, the Royal College of Physicians of London, the University of London, the Apothecaries' Society, and the General Medical Council are not represented. The removal of these hindrances to the success of the work undertaken by the Civil Rights Defence Committee is so important that it is desirable to enlarge upon those which are still in operation.

As the case stands, there is no security for the enjoyment of the liberties and rights which are the heritage of Englishmen or for the special professional rights of medical men. The latter may be stated to be the following: (1) the exclusive right to practise the medical profession for remuneration according to its customs and ethics in peace, free from the illegal institution of vexatious or speculative actions at law or other violence or disturbance; (2) the exclusive right to recover at law remuneration for professional work and services rendered; and (3) the right to refuse to attend in any case whatever—to refuse to attend unless satisfied of payment or if payment is refused or evaded; to refuse to attend or discontinue attendance for any reason that appears to render such a course desirable. If it be objected that the complaints of Mr. Anderson are injuries done to one man by the malice of the judges in a distant colony, and are never likely to be, never could be, repeated in this country, if even in any colony, it must be remembered that—1. The only appearance of redress or protection was obtained by the action brought in England against the offending colonial judges and by means of the right conceded by Justices Cave and Charles to sue the judges and to take the case to a British jury, on the ground that illegal and malicious acts done by a judge are *not* judicial acts. But it is now declared by the judgment of the Court of Appeal in Anderson *v.* Gorrie that all, even the most extreme violation of Mr. Anderson's rights were (*a*) judicial acts and (*b*) were not actionable, and (*c*) that Mr. Anderson had no right to go to a jury and (*d*) therefore had no right to protection. Judicial acts are acts done by authority of the Crown wielded by the judge. 2. Under this decision any judge may do any illegal injury to anyone in disfavour, may instigate the most frivolous and baseless claim or counter-claim, and on it may deprive a medical man of his earnings, give punitive damages against him, and seize his goods and imprison him to make him pay. All these injuries were done to Mr. Anderson and all are declared now to be judicial acts. 3. The right of remedy by suing for compensation and redress and submitting the claim to a jury is by this decision absolutely taken away in case of the injury being accomplished by the agency of a judge who, in depriving us of our rights to charge or recover, and in punishing us for refusing to attend for nothing or when insulted, is now declared to be using the authority of the Crown.

Digitized by Google

It is clear, then, that if perversions of justice by judges, if malicious acts by judges are to be called judicial acts, if all the charters of our liberties may be violated by judges with impunity, the right to sue for compensation being taken away, the subject and the professional man are left without protection from wrong and without any means of obtaining remedies for injuries wilfully, wantonly, and illegally inflicted. But this being contrary to the fundamental maxim that there is no wrong without remedy it becomes necessary for some other remedy to be devised. It may be that actions against judges are inexpedient and that they should be punished only by the Crown or by Parliament, but no punishment, such as removal from office, inflicted on a judge affords compensation to the person injured by the illegal acts of a judge, and, therefore, if for sound reasons of State the right to sue the judge be abrogated, it remains for Parliament to provide the means of redress to the injured individual. The Civil Rights Defence Committee is not wedded to any particular course, but is only interested in securing the means of remedy for admitted wrongs.

With regard to the objections raised to medical men recovering fees by law, entering into stipulations as to fees before attendance on patients, to their refusing to attend and withdrawing from a case before the completion of the attendance, the following considerations may be adduced. The rights involved in these conditions are elementary and fundamental. The right to charge *at all* is *lost* if the right to *recover at law* is lost, for, though many seldom or never use the right to recover at law, it is because of its existence that they are paid by numbers who otherwise would never pay. In Mr. Anderson's case even the right to stipulate to be paid and the right to decline to attend unless on an understanding to be paid were absolutely denied by the court. If these rights do not exist or are not to be exercised the medical man could not, without incurring punitive damages or imprisonment, refuse to pay a second visit till paid for the first, could not refuse the first visit to a patient who had deprived him of his honorarium in a previous illness, and must continue to visit the patient though he were vilified and insulted at every visit, and be solaced on seeking remedy by the comforting declaration that the act being that of the judge no rights had been violated and that he must rest content. Mr. Anderson was punished by damages and imprisonment and was sold up and ruined for exercising the elementary rights of a medical practitioner. If these rights are not to exist on the side of the medical man the opposite rights must belong to the public, and medical men would become the slaves of all who demanded their services.

The hindrance resulting from the disinclination of medical authorities and corporations to join in the work of the Civil Rights Defence Committee must be met by the inculcation of a higher standard of obligation on the part of these bodies. The case stands thus. The Crown has granted charters to the licensing bodies authorising them to confer diplomas or qualifications to practise the medical profession, and these diplomas convey certain definite rights and privileges. To obtain these diplomas and rights pupils flock to the medical schools, become candidates for the diplomas of the corporations, and when successful register their qualifications at the offices of the General Medical Council, by which they obtain the security of an Act of Parliament for the right to recover their fees if necessary in a court of law. The schools with their staffs, the corporations with their examiners, and the General Medical Council subsist upon the fees which they receive from the students and medical practitioners who obtain their diplomas and the rights conferred by the diplomas and by the registration of their diplomas in return for their work and their fees. In the light of Mr. Anderson's case, the supposed rights held out by the schools, corporations, and General Medical Council become empty and valueless promises, and the schools, corporations, and General Medical Council will become channels or agents of false promises. Mr. Anderson's case—and unless the decision is annulled there may soon be others like his in the future—illustrates as clearly as any case can illustrate the moral obligation resting on the schools, corporations, and General Medical Council to unite in resisting an invasion of the rights by traffic in which they themselves subsist, since by consenting to it they would consent to be agents for, and to profit by, conferring supposed rights which when relied upon may be, as they have been in Mr. Anderson's case, formally declared to be inoperative and valueless. If this is once understood and public attention is secured great public bodies with reputations to preserve will feel it to be impossible to accept so discredited and dishonourable a position, and will take their share with other public and professional bodies now engaged in the defence of these rights, now endeavouring to raise funds for the purpose of testing by appeal to the House of Lords the validity of the judgment of the Court of Appeal, and, should such appeal fail, determined to secure the correction of so great an evil by the action of the Legislature. To secure the coöperation of the medical schools, the corporations generally, and the General Medical Council would ensure success to the cause and would no doubt lead to the establishment of a recognised method and system of coöperation that would be of general and far-reaching advantage to the profession and the public.

(To be concluded.)

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE REPRESENTATION OF THE MEMBERS OF THE COLLEGE ON THE COUNCIL.

IT will be in the recollection of our readers that at the meeting of the Council of the Royal College of Surgeons of England, held on March 12th, the following resolution was passed by a small majority:—"That as the members of this Council represent the body corporate of this Royal College and consequently its Members as well as its Fellows, it is the opinion of this Council that no further representation of the Members is desirable." A discussion on the subject of the resolution, passed by the Fellows of the College at their half-yearly meeting in January by a large majority, in favour of according representation on the Council to the Members of the College, had taken place at the meeting of the Council in February, and this discussion resulted at first in the adoption of a resolution to take a poll of the Fellows on the question, but by a subsequent decision of the Council to take into consideration at the March meeting the question whether Members should or should not be directly represented on the Council before consulting the Fellows the poll was set aside altogether. It was with sincere regret that we chronicled both the adverse resolution of the Council to the Members' claims in face of the important vote of the Fellows at the January meeting and the loss of the resolution that a poll of the Fellows should be taken, and after reviewing the position and merits of the question of the representation of the Members on the Council and the state of opinion in the Council itself, as shown by the suspended minutes, we expressed our belief that it would not be surprising if these decisions should be reviewed and possibly rescinded at an early date. We are glad to be able to state that the whole subject will be reopened at the meeting of the Council on May 14th. At the March meeting of the Council Mr. Tweedy gave notice of the following motion for the meeting of the Council in May—viz.:—

"That a poll of the Fellows be taken respecting the motion passed at the general meeting of Fellows on Jan. 2nd in favour of giving to the Members of the College direct representation upon the Council, and that a committee be appointed to prepare for the approval of the Council an elucidatory statement of the subject in question together with the interrogatories which shall be submitted to the Fellows." A further step was taken at the quarterly meeting of the Council on April 9th, when Mr. Rivington gave notice that he would move at the May meeting:—

"That the following resolution, proposed by Sir William MacCormac, seconded by Mr. Bryant, and carried by 11 votes to 8, be rescinded—viz.:—

"As the members of this Council represent the body corporate of this Royal College, and consequently its Members as well as its Fellows, it is the opinion of this Council that no further representation of the Members is desirable."

Opinion upon the Council on these questions appears to be so evenly balanced that the result of the discussion will probably depend upon the accidental circumstance of the attendance or non-attendance of particular members of the Council. Half the Council voted on a former occasion in

Digitized by Google

favour of consulting the Fellows, and just less than half at the March meeting sufficed to negative the principle of representation of Members of the College on the Council. This is an anomalous condition of things, and it is obvious that even if the Council does not adopt Mr. Rivington's motion to rescind the resolution passed at the March meeting the exclusion of Members of the College from a voice in the management of the College which they do so much to support cannot be of any long continuance when they have a majority among the Fellows attending a meeting at the College and half the Council in their favour. We cannot but think that there could not be a more favourable time than the present to settle this much vexed question. A moderate concession now would be accepted by the Society of Members who are prepared, we understand, to give a fair trial to any measure agreeable to the Fellows and the Council, and it will be assuming a weighty responsibility to let the opportunity slip of uniting the Council, the Fellows, and the Members as they have never been united in the history of the College since 1843.

THE CONVERSAZIONE OF THE ROYAL SOCIETY.

THE annual conversazione of the Royal Society, held in Burlington House last Wednesday, when Sir Joseph Lister presided and received many distinguished Fellows and visitors, was from a spectacular point of view less striking than the exhibitions of preceding years. This was probably due to a great extent to the almost complete absence of purely electrical display. Not even the familiar crack of long sparking could be heard, but only the buzzing and comparatively unalarming sound of the induction coils employed in lighting up the Crookes's tube in the new photography. Photography, indeed, seemed to be the favourite subject of demonstration. That section of it now described as "new" was, as might have been anticipated, well represented by Messrs. A. A. C. Swinton, Mr. Herbert Jackson, and Mr. Sidney Rowland, the first two gentlemen adding some very effective experiments by means of the fluorescent screen. There was, however, nothing demonstrated which showed any important advance in the application of the "x" rays to medicine beyond what has already been published in THE LANCET. Turning to ordinary photography the prints exhibited by Professor Worthington were remarkable examples of the pitch to which instantaneity of photography has been brought. He showed photographs of the splashes produced by a falling drop of water, taken with the electric spark, the exposure being less than three-millionths of a second. The resulting pictures are very curious and interesting in pourtraying the disturbance. Progress in photography was also charmingly illustrated in Mr. Ives' exhibition of his stereoscopic photo-chromoscope, an instrument which records and reproduces colours more perfectly than the phonograph does sounds. The pictures shown were of singular beauty and most realistic. Mr. Friese Greene showed a rapid photographic printing machine at work which threatens to revolutionise the art of illustrating journals. The machine produces prints wholly or partly by photography, the chief object being to effect a very rapid production of copies adapted for use as illustrated supplements in newspapers, magazines, or for other purposes where a large number of copies of the same picture, design, or other objects are required. Thus it is possible to "run off" several thousand excellent photographic prints in an hour at an initial cost of a farthing each print.

Professor Clowes exhibited his ingenious apparatus for the detection of inflammable gas in electric culverts. In principle it is the same as the lamp used for measuring the amount of gas in the air of coal mines, and it is obviously adapted also for detecting and measuring the inflammable gas in inaccessible places, as in gasworks, coal-bunkers, and furnace flues. Professor Boys presided over the fragments that were left of the steel gas cylinders which were recently the subject of experimental inquiry which had its origin in the Fenchurch-street explosion. The report ultimately issued showed (1) the danger of using hard or unannealed steel for gas cylinders; (2) the extraordinary amount of violent ill-treatment to which a good soft annealed cylinder may be subjected without destruction, even when charged to 120 atmospheres; (3) the effect of very great internal pressure steadily applied; and (4) the violently destructive character of the explosion of mixed gases under pressure, which no practicable cylinder can withstand. One of the most interesting novelties in the exhibition was the "aërator" shown by Messrs. Read, Campbell, and Co. It consists of a sheet-steel bulb, not quite so large as a pigeon's egg, and containing compressed carbonic acid gas. The soda water bottle being filled with water, the "aerator" is inserted in the stopper, the closing of which liberates the gas by piercing the bulb. A few shakes complete the process, and excellent soda-water is thus quickly obtained. There is certain to be a successful future for this ingenious device. It is the best and simplest method of extemporaneously obtaining aerated water with which we are acquainted, and, further, is not expensive, the "aërators" costing probably not more than 6*d*. a dozen, and each being sufficient to make a "large soda." The "aërators" may also obviously be charged with other gases, the application of which for medical purposes is probable. Professor Roberts Austen of the Mint showed a simple and pretty experiment. By passing a current of thirty ampères through an aluminium wire a coating of oxide is almost instantly formed, which enables the temperature to be carried far above the melting point of the wire without breaking it. In fact the film of oxide serves as a pipe to contain the fluid metal. On approaching the wire with a magnet it twists about in a curious fashion, as though it were a thread of silk being turned. Specimens of boring marine animals were exhibited by the Marine Biological Association; while Mr. Walter Garstang, M.A., showed certain adaptations subservient to respiration in sand-burrowing Annelids and Crustacea. In aquatic animals which burrow in fine sand the activity of the gills would be impaired by the accumulation of sand around the gills, or in the course of the respiratory currents. To prevent this, the water before passing to the gills is "sieved" in the Annelid Aphrodite by a felted mass of fine hairs, and in Decapod Crustacea by the hairs bordering the branchiostegite. In the crabs Atelecyclus and Corystes the normal respiratory current is reversed and the water passes to the gills through a sieve-tube formed by the interlocking of rows of special hairs on the apposed antennæ.

The lantern demonstrations in the meeting-room were devoted to the beautiful colour photographs of Professor Lippmann taken by the interferential method. Later in the evening the same room was occupied by Professor Dewar, who repeated many of his remarkable experiments with liquid air at the Royal Institution.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6438 births and 3838 deaths were registered during the week ending May 2nd. The annual rate of mortality in these towns, which had been 19·0 and 19·5 per 1000 in the two preceding weeks, declined again last week to 18·4. In London the rate was 18·5 per 1000, while it averaged 18·4 in the thirty-two provincial towns. The lowest rates in these towns were 8·6 in Burnley, 11·3 in Brighton, 12·4 in West Ham, 13·9 in Bradford, and 14·1 in Cardiff; the highest rates were 20·4 in Oldham, 21·9 in Sunderland, 26·4 in Swansea, 26·9 in Manchester, and 28·7 in Salford. The 3838 deaths included 640 which were referred to the principal zymotic diseases, against 635 and 699 in the two preceding weeks; of these, 258 resulted from measles, 204 from whooping-cough, 67 from diphtheria, 42 from "fever" (principally enteric), 36 from scarlet fever, 30 from diarrhœa, and 3 from small-pox. No fatal case of any of these diseases was recorded in Burnley; in the other towns they caused the lowest death-rates in Norwich, Preston, Plymouth, and Leeds, and the highest rates in Croydon, Salford, Sunderland, and Oldham. The greatest mortality from measles occurred in London, Bristol, Manchester, Croydon, Oldham, and Sunderland; from scarlet fever in Salford; from whooping-cough in London, Manchester, Bradford, Salford, Bolton, and Croydon; and from fever in Halifax. The 67 deaths from diphtheria included 36 in London, 5 in Liverpool, 4 in West Ham, 4 in Birmingham, 3 in Hull, and 3 in Newcastle-upon-Tyne.

Digitized by Google

Two fatal cases of small-pox were registered in London and 1 in West Ham, but not one in any other of the thirty-three towns. There were 13 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 2nd inst., against 16 at the end of each of the two preceding weeks; 3 new cases were admitted during the week, against 5, 4, and 8 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2523, against 2587, 2527, and 2534 on the three preceding Saturdays; 236 new cases were admitted during the week, against 226, 201, and 236 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 328 and 287 in the two preceding weeks, rose again last week to 292, and were 53 below the corrected average. The causes of 52, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Oldham, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·0 and 19·0 per 1000 in the two preceding weeks, declined again to 19·0 during the week ending May 2nd, but was 0·6 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·9 in Leith and 17·7 in Edinburgh to 22·2 in Perth and 22·8 in Paisley. The 556 deaths in these towns included 30 which were referred to whooping-cough, 18 to diarrhœa, 11 to measles, 9 to "fever," (principally enteric), 6 to scarlet fever, and 2 to diphtheria. In all, 76 deaths resulted from these principal zymotic diseases, against 56 and 67 in the two preceding weeks. These 76 deaths were equal to an annual rate of 2·6 per 1000, which was 0·5 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 21 and 30 in the two preceding weeks, were again 30 last week, of which 14 occurred in Glasgow, 7 in Aberdeen, 4 in Edinburgh, and 3 in Paisley. The 18 deaths from diarrhœa showed a further increase upon recent weekly numbers, and included 9 in Glasgow and 4 in Edinburgh. The fatal cases of measles, which had been 9 in each of the two preceding weeks, were 11 last week, of which 8 occurred in Glasgow and 2 in Dundee. The deaths referred to different forms of "fever," which had declined from 12 to 4 in the three preceding weeks, rose again to 9 last week, and included 2 each in Glasgow, Edinburgh, Paisley, and Greenock. The fatal cases of scarlet fever, which had increased from 5 to 10 in the four preceding weeks, declined again to 6 last week, of which 3 occurred in Glasgow and 2 in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 109 and 120 in the two preceding weeks, declined to 88 last week, and were 36 below the number in the corresponding week of last year. The causes of 52, or more than 9 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·6 and 23·3 per 1000 in the two preceding weeks, further rose to 23·7 during the week ending May 2nd. During the past five weeks of the current quarter the death-rate in the city has averaged 23·7 per 1000, the rate during the same period being 19·1 in London and 17·6 in Edinburgh. The 159 deaths registered in Dublin during the week under notice showed an increase of 3 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against numbers declining from 10 to 4 in the three preceding weeks; of these, 6 resulted from scarlet fever, 2 from whooping-cough, 1 from "fever," and 1 from diarrhœa, but not one either from small-pox, measles, or diphtheria. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 3·9 in London and 2·1 in Edinburgh. The fatal cases of scarlet fever, which had been 2, 4, and 1 in the three preceding weeks, rose again to 6 last week, and exceeded the number recorded in any week during the past eight years. The 2 deaths referred to whooping-cough were within one of the number in the preceding week. The 159 deaths registered in Dublin last week included 22 of infants under one year of age, and 29 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from those recorded in the preceding week. Six inquest cases and 7 deaths from violence were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of 5, or rather more than 3 per cent., of the deaths in the city last week were not certified.

THE PUBLIC HEALTH IN THE FIRST QUARTER OF 1896.

The Registrar-General's Quarterly Report for the first three months of this year has exceptional interest. It shows the effect on the public health of a winter of almost unprecedented mildness. During each of the five months ending with March last a considerable excess of temperature prevailed, which averaged more than 3°F for the whole period. The annual death-rate in England and Wales during the first quarter of this year was so low as 17·9 per 1000, and not less than 3·9 below the mean rate in the first quarters of the ten preceding years. The death-rate was far lower than that recorded in the first quarter of any previous year since civil registration was established in 1837. The nearest approach to so low a rate in the first quarter of the year was 19·7 in 1884 and in 1893. The remarkably low death-rate last quarter would have been still lower except for an excessive mortality from the principal zymotic diseases, mainly due to the fatal prevalence of measles and diphtheria. As might naturally be expected, the exceptional mildness of last winter most favourably affected the mortality of persons aged upwards of sixty years. The annual death rate among persons at this group of ages did not exceed 69·2 per 1000, whereas the mean rate at the same ages in the corresponding periods of the preceding ten years was 95·4. Thus the mortality among persons aged upwards of sixty years was 27·5 per cent. below the average last quarter; whereas among infants under one year of age the decrease was only 4 per cent., and among children and adults aged between one and sixty years only 15 per cent. The death-rate in towns last quarter showed even more than its accustomed excess on the death-rate in rural districts. In other words, the mildness of the winter appears to have more favourably affected rural than urban districts. The death-rate in the aggregate town districts of England and Wales was 18·4 per 1000 last quarter and 3·9 below the average; while in the country districts the rate was only 16·6 and was 4·2 below the average. Thus during last quarter the urban rate was 11 per cent. in excess of the rural rate, whereas the average excess in the first quarter of the ten preceding corresponding quarters was only 7 per cent. This result is obviously due in great measure to the fact that in country districts the population includes a far larger proportion of elderly persons than it does in urban districts, and we have seen that the mild winter most favourably affected the mortality of elderly persons. The main feature of the mortality returns just issued as regards zymotic disease was the exceptional fatality of measles, the annual death-rate from which during the quarter was 0·70 per 1000 and 0·27 above the average rate in the first quarters of the previous ten years. This rate from measles was 0·96 in the 100 largest towns, while in the remainder of England and Wales it was less by one-half, or 0·48 per 1000. Among the largest towns the rate was 1·82 in Leicester, 2·10 in Salford, and 3·25 in Norwich. Still higher rates prevailed in some of the smaller towns. Diphtheria, although far less fatal than measles, showed a larger increase in the death-rate compared with the ten years' average. The highest death-rates from this disease occurred last quarter in London and its suburbs, Birmingham, Wolverhampton, and Halifax. If we exclude the exceptional fatality in the metropolitan district, the death-rate from diphtheria was almost identical last quarter in the urban and in the rural groups of districts. Small-pox caused 192 deaths in England and Wales last quarter, of which not fewer than 144 occurred within the city of Gloucester. The mortality from whooping-cough, scarlet fever, and enteric fever was in each case below the average. In conclusion, the remarkable further decline in the birth-rate calls for notice. Notwithstanding the recent recovery in the marriage-rate the

Digitized by Google

birth-rate in England and Wales last quarter was unprecedentedly low and was only equal to 29·1 per 1000. This rate was 2·6 per 1000 below the mean rate in the ten preceding corresponding quarters, and 3·0 below the rate in the first quarter of last year. The decline in the English birth-rate is an increasing decline. In the four last periods of five years the birth-rate has successively averaged 35·4, 33·5, 31·4, and 30·5 per 1000. Thus in its effect on the population of England and Wales the constant decline in the death-rate is neutralised by the equally constant decline in the birth-rate.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

THE following officers have arrived from India on completion of a tour of service:—Surgeon-Lieutenant-Colonel Donovan and Surgeon-Majors Hart, Swabey, and Mosse. Surgeon-Captain Shaw has embarked for South Africa. Brigade-Surgeon-Lieutenant-Colonel Brown and Surgeon-Majors Donaldson and Tidbury have been appointed to Cork, Surgeon-Major Cusack to the Curragh, and Surgeon-Major Cowen and Surgeon-Captain Carter to Dublin.

ARMY MEDICAL STAFF.

Surgeon-Major-General Sir William Alexander Mackinnon, K.C.B., Q H S., Director-General, Army Medical Department, is placed on retired pay. Surgeon-Major-General J. Jameson, M.D., has been appointed Director-General, Army Medical Department, vice Surgeon-Major-General Sir W. A. Mackinnon. Surgeon-Colonel Alexander F. Preston, M.B., to be Surgeon-Major-General, vice J. Colahan M.D., retired. Brigade-Surgeon-Lieutenant-Colonel George J. H. Evatt, M.D., to be Surgeon-Colonel, vice A. F. Preston, M.B. Surgeon-Lieutenant-Colonel John Dallas Edge, M.D., F.R C.S. Irel., to be Brigade-Surgeon-Lieutenant-Colonel, vice J. H. Reynolds, V.C., M.B., retired. Surgeon-Lieutenant-Colonel Charles E. Dwyer to be Brigade-Surgeon-Lieutenant-Colonel, vice G. J. H. Evatt, M.D.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Surgeons: C. Strickland to the *Mohawk;* W. G. Stott to the *Magnificent;* P. N. Randall to the *Victory*, additional for the *Duke of Wellington;* and A. G. Wildley to the *Cruiser*. Surgeon and Agent: W. J. Shaw at Redheugh.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain David Thomson, M.D., to be Surgeon-Major.

YEOMANRY CAVALRY.

Nottinghamshire (Southern Nottinghamshire): Henry Williams, gent., to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Hampshire (Southern Division, Royal Artillery): The appointment of Mr. E. F. Eliot as Surgeon-Lieutenant is cancelled at his own request. 1st Caithness: Surgeon-Lieutenant-Colonel G. Banks, M.B., resigns his commission, but is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. 2nd Glamorganshire: Surgeon-Lieutenant A. Hood, M.B., resigns his commission. *Rifle:* 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Captain C. W. Philpot, M.D., resigns his commission.

THE OUTBREAK OF ENTERIC FEVER AT ALLAHABAD.

The *Pioneer Mail* of April 16th gives an account of a recent outbreak of enteric fever in this cantonment. It seems that the disease began in the autumn of last year in the Royal Irish Fusiliers. The corps moved in relief to Burma, and was succeeded by the Norfolk regiment, in which after some weeks' interval a few cases of the disease occurred in February of the present year, and these were followed by others at a later date. Up to the present time forty-seven cases and upwards of twenty deaths have occurred. Allahabad is stated to have probably the best managed dairy-farm in India, and it has water-works which recently cost between twenty and thirty lakhs of rupees. Mr. Hankin, the Government bacteriologist, has recently made a searching investigation into the causes of this severe outbreak. The pipe-water as drawn from the taps has been found to be excellent, and that drawn directly from the barrack-room filters was also good, but the water in the *surais* on being subjected to a bacteriological examination was found to be most impure. The subject is still under investigation, and we shall probably learn subsequently more about it; meanwhile we must content ourselves with a bare statement of the facts as given by our contemporary.

THE MATABELE RISING.

The news connected with the Transvaal crisis has been of so exciting a character of late that it has for the most part absorbed public attention to the exclusion of the events connected with the Matabele rising. The inhabitants of Bulawayo seem to be quite capable of holding their own until the arrival of reinforcements; indeed, it is stated that owing to the successful attacks that have been made upon the Matabeles the neck of the insurrection is broken, and that all danger will probably be over before the arrival of the Imperial troops at Bulawayo. The forces proceeding to its relief have, owing to the prevalence of cattle disease, to encounter great difficulties in the way of transport and supplies. The wounded in Bulawayo are reported as doing well.

CHOLERA AT CALCUTTA.

Cholera has been unduly prevalent of late in Calcutta. During the week ending April 4th there were 235 deaths from cholera, against 179 and 114 in the two preceding weeks. The number is higher than the average of the past quinquennium by 180. To arrest the progress of this disease at Tarkessar the Commissioner of the division prohibited the East Indian Railway authorities from running special trains during the time the great fair was held there last month. According to Indian experience cholera may be expected to prevail early in the year in the eastern districts and late in the year in the western districts of the province. In Lower Bengal, when the surface is under water, cholera is extinguished as a fire would be.

THE MEDICAL STAFF CORPS.

The Director-General, Sir William Mackinnon, K.C.B., in issuing his last corps order, has expressed his farewell wishes to all ranks and also his appreciation of the work done by them during his tenure of command. He earnestly trusts that each soldier will always endeavour to uphold the reputation of the Medical Staff Corps and do his utmost to maintain its efficiency both in peace and war.

DEATH IN THE SERVICES.

Mr. James Flanagan, L.R.C.S.Irel., R.N., Deputy Inspector-General of Hospitals and Fleets (retired), at Portsmouth, on the 30th ult., aged sixty-one. He was Assistant Surgeon in charge of the *Shannon* Naval Brigade during the Indian Mutiny (Indian medal and clasp), and was specially promoted for his services.

His Excellency the Commander-in-Chief has accepted the invitation of the senate of the Army Medical School to preside and distribute the prizes at the termination of the present session of the Army Medical School.

Three hundred and eleven patients were admitted to the Royal Victoria Hospital, Netley, on April 28th *ex* H.M.'s troopship *Malabar* from Bombay. This was the last voyage of the *Malabar* as H.M.'s troopship.

ABERDEEN UNIVERSITY BUILDINGS EXTENSION.—The special effort made to raise £10,000 before May 1st, so as to secure Mr. C. W. Mitchell's subscription of £6000, was successful, £200 above the sum required having been contributed at that date. The scheme was inaugurated in 1891, and the total sum collected up to May 1st was £109,365 8*s.* 10*d.*, made up as follows: General public (including £10,000 from the Aberdeen town council), £42,365 8*s.* 10*d.*; Government, £40,000; the late Dr. Charles Mitchell, Jesmond Towers, £21,000; and Mr. C. W. Mitchell, Jesmond Towers, £6000. The £16,000 referred to will go towards the erection of the south wing at Marischal College. Good progress is being made with the north wing. More money is required to complete the scheme and no final answer to the application to Government for a further grant of £40,000 is expected for about three months. Meantime additional subscriptions from private sources continue to come in. Should the funds permit of the scheme being carried out in its entirety Marischal College will be the largest and finest granite building in the United Kingdom.

"Audi alteram partem."

"THE REGISTRATION OF MIDWIVES."

To the Editors of THE LANCET.

SIRS,—I can perhaps give no higher praise to the admirably wise and judicial deliverance in your issue of April 25th upon the above subject than to say that it is worthy of the reputation of the Editors of THE LANCET. As I have had the misfortune—as a punishment for my sins, I suppose—to become interested in the midwives question I crave your indulgence in order to place before your readers some thoughts which have occurred to me in connexion therewith. It has been the grave misfortune of the British Medical Association, in attempting to deal with this important subject, that it has apparently derived both its inspiration and its ideas from the Midwives' Institute, and that, so far as I can judge, the matter has been but little considered either from the standpoint of our profession or that of the public. In what I desire to say on the subject I shall endeavour, as far as possible, to do justice to all three. In connexion with any proposed legislation the initial point to determine is the achievements to be aimed at, and in connexion with the present matter I regard these as mainly three in number:—1. To help and protect the poor. As labour of this kind is familiar to every member of our profession from his professional cradle to his very grave, I feel sure that any wise proposals in that direction will meet with nothing but a generous and hearty response from every one of us. 2. To maintain the just rights and liberties of the profession. The Medical Act of 1886 was, I understand, passed into law in the interests of the public and in order to protect them from the dangers arising from the employment of partially and incompletely educated medical practitioners. These dangers are quite as real to-day as they were in 1886, and midwifery certainly ought not to be the least important part of a medical man's training. The door of our profession stands as widely open for women as it does for men and all are welcome who enter in that way; but attempts to get over the wall (as proposed by these Midwives Registration Bills) are sometimes devoid of an honest intent and ought to be very carefully attended to. 3. To deal justly with so-called midwives. The extensive employment of these women by the poorer members of the community has rendered them an apparent necessity of our civilisation, and the wise course for our profession to pursue is to recognise the fact and deal fairly and honestly with the same. Having thus indicated the chief objects to be aimed at in any proposed legislation, I pass on to consider very briefly the principles which should guide that legislation, and these, also, are in my opinion mainly three:—1. To maintain the Medical Act of 1886. This I have already dealt with, and it does seem to me that the profession which is not prepared to defend and maintain its lawful rights and privileges never deserved to have any. 2. The local registration of midwifery nurses by the medical officer of health. The advantages of such a course as distinguished from the creation of a national register for these women seem to me to be as follows. (*a*) It meets the circumstances of the case. When I reflect that there are from 20,000 to 30,000 midwives in England and Wales, and that on an average the professional training of these women has probably cost less than a five-pound note, the need for a national register in order to conserve an educational training of that value is not apparent, and such a register in their case would be very likely to bring national registers into contempt. (*b*) It would be efficient. There is little doubt that as far as it goes our sanitary service deserves this character. In urban districts, where the medical officer of health is exclusively devoted to the duties of his office, there is no doubt that he would deal perfectly justly with these women, and would, in his desire to keep down his puerperal mortality, exercise upon them an enormous influence for good. We should have in this case direct medical supervision in the best and I believe the only possible sense. Where the medical officer of health is engaged in general practice safeguards against injustice ought to be provided by permitting an appeal either to the medical officer of health for the county or to some other impartial authority. (*c*) It would be cheap because the machine for its administration is already in existence. The creation of an administration anything like so efficient in connexion with a national register would annually cost an enormous sum of money. (*d*) It would be a register for sanitary purposes only, and I confess that with the best intentions possible I quite fail to see what just claim existing midwives have to anything more exalted. 3. The training of the midwifery nurse. Nursing is essentially a practical matter, involving little or no theory, and the training should for that reason be as far as possible practical also. There is a real danger of the training of these nurses being pitched too high, and I consider that six months' residential training in a public lying-in hospital or union infirmary, where there are not less than fifty confinements per annum, conducted in every case under the direct supervision of the resident medical officer, would meet the requirements of the case.

These are, Sirs, it seems to me, the main principles to be held in view in connexion with any proposed midwifery legislation, but there are several others of great but secondary importance. No medical practitioner, for example, should be permitted to undertake the training of these women until he has satisfied the General Medical Council as to his capacity to comply with the requirements of the Act, and he should be responsible to that body for the discipline and efficiency of the training imparted. The question of an examination is also important and one requiring careful consideration. I have little confidence in, and less admiration for, midwives' examinations as hitherto conducted, and I believe that this much over-done ceremony might in their case be dispensed with with advantage. The British public are an extremely efficient set of examiners. In any case the setting up under legal authority of special examining boards for the exclusive use of these women is, in my opinion, an error of judgment. If the General Medical Council is fit to govern the great profession of medicine it is quite competent to deal efficiently with such a trifling matter as the examination of these midwives, and the whole matter should be left in its hands. Having received her training it would be possible for the midwifery nurse to follow one of two courses—viz., either to go out as a monthly nurse under a medical practitioner (in which case her training would be an inestimable help and boon to him and a very distinct and palpable advantage to the public) or she might at once—or after a year or two's experience as a monthly nurse—get registered by the medical officer of health and undertake the duties (subject to the sanitary and other conditions furnished her by that official) now discharged by so-called midwives. When so registered the midwifery nurse would, of course, only attend cases devoid of complications within the meaning of the Act.

When I consider, Sirs, the average cost of the training of existing midwives—on an average certainly not more than £5—and also consider that in the Act suggested the cost would probably not exceed £10, and when I reflect upon the very substantial earnings of good monthly nurses and midwives, I entirely fail to see how under such an Act any injustice could arise to these women. This essentially sanitary scheme of registration has at least the advantages of being simple, of being cheap, and, for the purposes which it is intended to accomplish, of being efficient. If carried into law it would, in my opinion, do the profession no harm, it would do the better class of midwives some good, and it would very certainly materially reduce the puerperal mortality for England and Wales in the course of a few years. I should be very glad to be able to believe that some much more ambitious projects were capable of doing as much good and as little harm.

I am, Sirs, your faithfully,

Salford, April 27th, 1896. WILLIAM FRASER.

MATERNAL SYPHILIS.

To the Editors of THE LANCET.

SIRS.—Dr. Shaw-Mackenzie's courteous criticism of my first Hunterian Lecture calls for but short reply from me. The view that inherited syphilis in the infant is in every instance derived from the mother is, I should have thought, sufficiently refuted to need no further demonstration on the point. To have entered at any length on this part of the subject would have seemed to me equivalent to dealing with the proverbial "man of straw." I would readily grant that

Digitized by Google

transmission through the germ is much more easily comprehensible than that through the sperm, but I would contend that all facts confirm inheritance from the father independently of the mother. Some obscurity in my language has doubtless led to a misapprehension on Dr. Shaw-Mackenzie's part. I never intended drawing any percentage between the two sets of cases, in the one of which the mothers were apparently healthy and in the other undoubtedly syphilitic. Without having gathered any statistics on the point I should from personal impressions consider that the cases of inherited syphilis where the mother is apparently free outnumber those where she is obviously syphilitic by three or four to one. Dr. Shaw-Mackenzie's statistics from Mr. Henry Lee's note-books will be of interest. The value of their bearing on the point at issue, however, will be vastly discounted by the consideration that they probably only relate to women coming under notice for obvious syphilis. Dr. Shaw-Mackenzie's experience at children's hospitals probably furnishes the truer view of the state of affairs as regards the mothers of syphilitic infants in general. To one of his statements I must take strong exception, and this is that immunity to syphilis, partial or complete, is the equivalent of the acquisition of the complaint itself. I shall look forward with pleasure to the appearance of Dr. Shaw-Mackenzie's paper in your columns, and shall possibly find occasion to comment on it.

I am, Sirs, yours truly,

Upper Berkeley-street, May 5th, 1896. J. A. COUTTS.

"THE BRONCHITIS KETTLE AND POULTICES IN PNEUMONIA."

To the Editors of THE LANCET.

SIRS,—I am glad to see in THE LANCET of April 18th that Dr. F. de Havilland Hall draws attention to the treatment of acute lung affections, and in particular to the use of bronchitis kettles, poultices, and diet. It has too long been the custom to follow the stereotyped method without giving the matter that consideration which it deserves. For some time I have failed to see the *rationale* of the treatment of pneumonia with poultices, and consequently they are now banished from my list of remedies, with, I am convinced, much better results than I formerly obtained with them. To load a person's chest with an accumulation of evil-smelling and uncomfortable material whilst he is suffering from respiratory difficulties seems contrary to common sense, when to open the window and secure to him a breath of fresh air which he so much desires would much better meet the requirements of the case. If there is any advantage in a poultice, which I very much doubt, it is greatly outbalanced by the dangers of an ever-changing temperature in the region of the chest as must follow a succession of poultices. I have used Gamgee tissue now for some years and am satisfied that my results have fully justified its use. As far as diet is concerned, in cases of pneumonia I believe in giving the patient a fairly free scope; during the acute stage there is usually a dislike for food of any kind, and to try to force it at painfully regular intervals seems more cruel than kind. To give an instance, I have recently had a case of pneumonia in a child four years of age. The temperature stood at 105° F. for ten days; there was complete anorexia during the whole period, so I ordered milk with a little lime-water, cold water, and barley-water; these satisfied the patient's craving for liquids and being cold were more acceptable. The mother, fearing the child would become exhausted, gave some sickly preparation resembling beef-tea, which was immediately expelled; the experiment was not again tried. On the eleventh day the temperature went down to 99°, the appetite returned, the tongue cleaned, and the recovery was a rapid one. The child's cry for solid food was gratified and no discomfort followed. The bronchitis kettle I have no experience of.

I am, Sirs, yours faithfully,

Darwen, April 30th, 1896. F. G. HAWORTH.

"THE NEW PHOTOGRAPHY."

To the Editors of THE LANCET.

SIRS,—In conjunction with Mr. John Aitken I have been working for some time at a means of shortening the exposure required for the new photography. We first tried painting a platino-cyanide solution on to the sensitive film, but found that it injured the emulsion and made the negative difficult to fix. We also tried various forms of interposed fluorescent screens which, though they much shortened the exposure, interfered with good definition. Lastly, in consequence of your article on the use of fluor-spar placed behind the film, we have made, with Mr. Bidwell's help, some experiments in this direction. I may sum up the results we have obtained as follows: celluloid negatives should be used in place of glass; the fluor-spar should be finely powdered and pressed well against the film; the fluor-spar should be thoroughly removed before developing; the exposure time is reduced to about one-third of the ordinary exposure; definition is not interfered with; calcium tungstate may be used in place of the fluor-spar and appears to exercise a more marked effect; and platino-cyanide screens may also be made use of.

I am, Sirs, yours faithfully,

DAWSON TURNER, M.D. Edin., M.R.C.P. Lond.,
Lecturer in Physics at Surgeons' Hall, Edinburgh.

George-square, Edinburgh, April 20th, 1896.

THE NILE EXPEDITION.

To the Editors of THE LANCET.

SIRS,—Having recently returned from the Nile I have read your article on Egypt with much interest. I fully agree with what you say concerning the sanitary condition of Cairo and some of the towns up the river, but I disagree with you as to the probable result of the advance of the Nile expedition. Aswân I consider one of the healthiest of the health resorts on the upper reaches of the Nile, but visitors have been constantly scared during the past winter by the Dervish raids which have taken place between Wady Halfa and Aswân. One of these raids took place while I was myself at Aswân, and I can assure you it very greatly accelerated the return of Europeans down the Nile. The Dervishes having the rich province of Dongola to fall back on, from which they draw their supplies, are able practically to make these raids with impunity. There will be no safety for the upper reaches of the Nile until the Egyptian Government holds Dongola. I therefore think that a military expedition to Dongola will aid instead of retard the sanitary and social conquest to which you refer by rendering safe the upper reaches of the Nile. It is no good going in for costly sanitary improvements with a view of attracting invalids until the frontier is safe—patients will not go where they are liable to constant scares from Dervishes. Thanking you in advance for the insertion of this letter in your valuable journal,

I am, Sirs, yours faithfully,

EDWARD STEWART, M.D. Brux., M.R.C.P. Lond.

East Grinstead, May 2nd, 1896.

SAFE *v.* DANGEROUS ELECTRIC LIGHT CURRENTS.

To the Editors of THE LANCET.

SIRS,—As I have always, from practical experience, contended that electric light and power can be more efficiently and economically supplied to towns and urban districts within a radius of five or six miles by using continuous currents rather than high-pressure alternating currents, I was, to settle as far as possible the question of danger, impelled to write to the Board of Trade for information. To my letter of inquiry they have courteously replied as follows: "In reply to your letter of the 9th inst. I am directed by the Board of Trade to state that they have been informed of nine cases of fatal accidents to employés at generating or transforming stations where high-pressure alternating currents are used, but that no instances have been reported in the case of low-pressure continuous currents." As the information received is of great public interest I trust you will see the desirability of making this known to your numerous readers.

I am, Sirs, yours truly,

Electric-avenue, S.W., May 4th, 1896. A. L. FYFE.

*** The Board of Trade have given the answer that might have been expected. To give the comparison any real value it should have been made between alternating and continuous currents having the same effective voltage. There are reasons for supposing that high-pressure continuous current of, say, 1000 volts—e.g., as at Oxford—would by its electrolytic effect prove more dangerous than a sinusoidal

Digitized by Google

current of the same effective voltage. It is true that the regulation which limits the low-pressure alternating current-supply to 250 volts and allows 500 volts for continuous current seems to imply that the former is the more dangerous. If the Board of Trade really hold this view the grounds upon which it is based have not, so far as we are aware, ever been made public. It may be that the idea is simply a survival of an opinion founded on certain "classic" experiments of Sir W. Siemens made in the days of comparatively crude machines; and, inasmuch as there may still exist in actual work certain alternators giving a very "peaked curve"—that is to say, whose maximum electro-motive force greatly exceeds the effective electro-motive force as registered by thermal or magnetic voltmeters—the rule in question is perhaps a useful one, allowing as it does for this margin of possible danger.—ED. L.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—At the last Liverpool Assizes an action for damages was brought against a medical practitioner in Wigan (Baucher *v.* Wright) for alleged negligence in the performance of his duties as club surgeon. The plaintiff received a severely contused wound of the hand, to which the defendant gave particular attention with a good result. Owing to an opinion that the metacarpal bone had been broken and that the fracture had not been discovered by the defendant the plaintiff entered an action claiming £250 damages. The verdict of the jury without leaving the box was for the defendant; but as the plaintiff is unable to pay the defendant's costs, which amount to nearly £150, a committee has been appointed with the object of raising this amount. Of course, it is to be regretted that the defendant did not belong to a medical defence union, but as he has successfully defended an action which should never have been brought we trust an appeal to his professional brethren will not be in vain. The committee—Mr. C. M. Brady (chairman), Mr. C. R. Graham, and Dr. Benson, and myself as secretary—will be pleased to receive any subscriptions and also will be grateful if you will kindly insert this appeal in an early issue of your valuable journal.

I am, Sirs, yours faithfully,

Wigan, May 4th, 1896. WM. BERRY.

The following subscriptions have been promised or received:—

THE RELIABILITY OF CLINICAL THERMOMETERS.

To the Editors of THE LANCET.

SIRS,—I was informed some time ago by the head partner of a firm of surgical instrument makers that clinical thermometers altered after two years, as a rule—viz., registered higher than they ought to do. I stupidly omitted to ask him if this applied to all thermometers, or only to those in constant use. Can you give me any information on the subject? If not, will you kindly submit the question to the readers of THE LANCET, as the subject is an important one?

I am, Sirs, faithfully yours,

Mediterranean, April 22nd, 1896. R.N.

*** All clinical thermometers are liable to read somewhat high after having the scale divided about two years, if the graduation has been made as soon as the instrument was constructed. Use has nothing to do with this, or at any rate nothing worth mentioning: the reason is that the bore of the unseasoned tube is liable to slightly contract. Messrs. Down Bros. guarantee that in none of their well-seasoned tubes will any change take place, not to the extent of one-fifth of a degree in five years. Messrs. Arnold and Sons inform us that they do not mark any tubes for graduation which have not been manufactured at least two years.—ED. L.

THE ARMY MEDICAL STAFF.

To the Editors of THE LANCET.

SIRS,—I know you have the interests of the Army Medical Staff at heart, and I therefore ask you to insert a short letter from one who, as a medical officer of over thirty years' service, must be fairly well informed on the subject on which he is writing. In the first place, I cannot imagine why army surgeons are supposed to be such very ignorant practitioners. In the Ashanti campaign of 1873 and of 1896 they proved themselves exceptionally able; in all the wars of the last forty years they have shown themselves to be not only good officers but also good medical men; in peace time the results of practice in military hospitals are, I am quite certain, as successful as in civil hospitals, and I am equally certain that the medical treatment soldiers receive in the army leaves little to complain of. Military surgeons are certainly not specialists in certain affections peculiar to women—it is quite out of their line, and always will be; neither are they the equals of the leading hospital surgeons, nor will they ever be, for they have not the enormous practice and experience these men have. We have, of course, duffers among us, and I need hardly say there are duffers in the civil community. We military surgeons who are behind the scenes know well what errors in diagnosis and feebleness of treatment frequently meet our view in civil life. I do not myself believe that discontent exists to any degree among our patients, though I am well aware that medical advice which can be obtained for nothing is very lightly valued by all classes, and I quite agree with you that it is neither fair to the patient nor to his surgeon that the latter should be frequently changed while in charge of a ward. Some changes in military service are absolutely necessary.

Now, with regard to military titles, we are not in the least ashamed of the title of "Doctor," nor are we in the least degree anxious to be taken for combatant officers; but as we lead an entirely military life, accompanying the soldier in all his campaigns, sharing to the full his hardships and dangers—for however big or small the expedition may be if it involves a risk to the soldier there is found the army surgeon ready at hand to afford help in case of trouble—we are military men in every sense of the word, though not combatant officers, and naturally desire to possess military titles, which show, not to military men only, but also to civilians with whom we associate, what rank we have earned and hold in the army. Such titles as were formerly in use do not convey this information, nor were they ever used except officially. A surgeon of one month's service and an inspector-general of thirty-five years' active service were both addressed simply as "Doctor." We object to this.

Now, in conclusion I should like to state my conviction as to the present unpopularity of the service. We are satisfied with our pay, our retirement, and rank, but the medical profession is disgusted with the abuse, the continual endeavour to degrade instead of elevate the medical service and to make its members ashamed instead of proud of it. In the service journals ridiculous and impossible yarns are fathered on medical officers such as could never have had any foundation in fact, but yet serve the purpose of raising a laugh at the service. These are the reasons why young practitioners will not come forward. Is the prospect enticing? The pay may be increased, that most questionable suggestion of short service may be adopted (the certainty of provision for life is really the only attraction the medical service has to offer), and any possible expedient may be tried, but until it becomes a career carrying with it not only all the hardships and dangers of military life, but also some of its prestige, competitors of a desirable class for commissions in the Army Medical Staff will never be obtained. The marvel to me is that, in spite of the treatment this branch of the service has for years received, medical officers can be found willing to throw away their lives cheerfully at the call of duty. I wonder if our opponents are aware that the fact was elicited at a Royal

Digitized by Google

Commission which inquired into these matters some few years ago—and whose suggestions by-the-bye, as they were favourable to the medical men, were never carried out—that the mortality among army surgeons was nearly double that of combatant officers? I do not think young medical men fear death as much as most other people, yet this can hardly be considered an additional inducement to enter an unpopular service. I am quite convinced that the endeavour to deprive army surgeons of their military rank earned by hard service in the field and to make them, as General Buller expressed it in his recent speech at Netley, merely an annexe to the army is at the bottom of the prevalent discontent, and until this is removed we shall never get good men to join the ranks of the Army Medical Staff.

I am, Sirs, yours faithfully,

April 17th, 1896. BRIGADE-SURGEON, A.M.S.

THE BATTLE OF THE CLUBS.—XXIX.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1171.*)

SHEFFIELD:—AN ANCIENT MEDICAL SOCIETY.—WORKMEN SWEATERS.—THE OLD GRIEVANCES.—PROBABLE FORMATION OF A MEDICAL UNION.

THE medical profession at Sheffield should encounter but little difficulty in forming a strong medical union to deal with ethical and economical questions. For social and scientific purposes the profession has already been united, and this for many years. There is still a minute-book extant which describes the fourteenth annual meeting of the Medico-Chirurgical Society of Sheffield held on Oct. 12th, 1848, so that the society was evidently founded so far back as the year 1834. The very age, however, of the society renders it more than usually difficult to depart from its customs and habits. Consequently it has very generally been decided that instead of extending the programme of the old organisation a new society must be created, but such an effort cannot be successful unless the old society lends active assistance. The Sheffield Medico-Chirurgical Society now numbers from 170 to 180 members and it may be said that almost every respectable practitioner in the town and neighbourhood belongs to this organisation; indeed, it would be difficult to find a town where the profession is so thoroughly united. Unfortunately this union has only been useful in promoting social intercourse, in fostering a friendly feeling between the members of the profession and in facilitating their medical researches and studies. Nothing has been done in the defence of their material interests. Yet we find here in Sheffield, as in other centres, the same complaint; the same exploitation of medical men by friendly societies and assurance companies as described with regard to other towns. Thus one of the first practitioners on whom I called related to me that he had recently sent to one of his patients, who lived at some distance from his surgery, a bill for £5 for medical attendance. A little time afterwards he received a letter from a life insurance company. The canvasser of this company had without any authority whatsoever given the name of my informant as the general medical attendant of the company, and the company now wrote to say that they thought three guineas would be an ample remuneration for the services rendered. Of course the medical practitioner protested that he knew nothing about the insurance company in question and could not admit that they had any right to interfere in his affairs; but his patient was at once surprised and disappointed to find that though he had insured his life he would have to pay the usual medical fees. Other men might have consented to the reduction in the hope that the insurance company would send them other patients, and have thus helped to bring about a general reduction in the fees usually given for medical services. It is a serious matter if canvassers of insurance companies are going to make use of the names of medical men without informing them of the fact and obtaining their authorisation.

Several of the friendly societies at Sheffield have formed an amalgamation and opened a dispensary of their own, where they used to employ a medical officer at, I believe, a salary of £200 a year. But the work gave rise to so many disputes that the medical officer left them, took away a number of their members, and started in private practice on his own account. His successors received a smaller salary, but they were allowed to engage in private practice. Nevertheless other disputes arose. Abuses are of course frequent. Thus a family who for several years had paid the usual 2*s.* 6*d.* per visit joined the Druids and now only pay 3*s.* a year. Practitioners who are officers of friendly societies often experience unpleasant surprises. One of these medical officers related to me that he had been called out to see a tradesman. For some considerable time he had to pay two visits per day. A consultant was called in to whom the tradesman gave a guinea fee. Then it appeared that the tradesman belonged to a friendly society and had recently caused his name to be transferred from the list of his usual attendant to the list of the medical officer who had been attending him so assiduously twice a day. Instead of about 5*s.* a day, which the tradesman could well afford to pay, my informant was destined to receive only 3*s.* a year. On another occasion he was called in to see a man who certainly had started in business in a very small way, but had prospered and now drove into town in his own carriage. When this patient died he left about £80,000. At first the medical officer treated this wealthy individual as if he was a private patient. Then he heard that he was a member of a club and did not propose to give any fees whatsoever. As medical officer of the club in question the medical man was obliged to continue the treatment, but he thought that, under the circumstances, he need not take the trouble of wrapping up the medicine bottles in paper. This it appears greatly offended the patient, who consequently did not come for any more consultations. Here, then, was a man possessing some £80,000 who was quite contented to go on paying only 3*s.* a year for medical attendance and yet was offended because he was treated like workmen and the poor people who alone have a right to demand medical attendance at such reduced rates.

One great difficulty in Sheffield arises out of the prevalence of the sweating system. In the cutlery trade foremen and other workmen contract for a certain amount of work. They only do a portion of this work themselves and give the rest out to other workers, charging them a commission for the work provided. It thus occurs that this sub-contractor or sweater often makes five and six times more out of the commissions he sweats out of the workers under him than he obtains for the work he does with his own hands. Apparently he is an artisan able to earn, perhaps, 30*s.* or 40*s.* a week by his work, and as such gains admittance as a member of a friendly society and claims medical aid when he is ill. But a case was pointed out to me of an artisan who, apart from his normal wages, secured in commissions £20 a week. These men dress as workmen, live in workmen's cottages, are apparently poor, hard-working men, but they drink champagne with their lunch. How can a wage limit be applied to this class? They are careful to conceal what they earn in the form of commissions. One such "workman" was pointed out to me who possessed £1000 in cash and had bought a considerable amount of house property. He was a member of a friendly society and would be very indignant indeed if it were suggested that he, "a poor working man," should pay the usual medical fees. He might live in a workman's cottage and wear cheap workmen's

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Aug. 24th, 1895, Brussels; (2) Aug. 31st, 1895, Brussels; (3) Sept. 21st, 1895, Portsmouth; (4) Sept. 28th, 1895, Portsmouth; (5) Oct. 5th, 1895, Eastbourne; (6) Oct. 12th, 1895, Lincoln; (7) Oct. 26th, 1895, Lincoln; (8) Nov. 2nd, 1895, Grimsby; (9) Nov. 9th, 1895, Bexhill-on-Sea; (10) Nov. 16th, 1895, Hull; (11) Nov. 23rd, 1895, Hull; (12) Dec. 7th, 1895, York; (13) Dec. 14th, 1895, Northampton; (14) Dec. 21st, 1895, Fermanagh Medico-Ethical Association; (15) Dec. 28th, 1895, Northampton; (16) Jan. 4th, 1896, Birmingham; (17) Jan. 18th, 1896, Birmingham; (18) Jan. 25th, 1896, Club Practices in Rural and Mining Districts; (19) Feb. 1st, 1896, The Formation of a Provident Medical Association at Folkestone; (20) Feb. 8th, 1896, The Manchester Medical Guild and Medical Aid Associations; (21) Feb. 15th, 1896, The Leicester and Leicestershire Provident Dispensary; (22) Feb. 22nd, 1896, The Organisation of the Profession at Leicester; (23) March 7th, 1896, Loughborough: Local Efforts Defeated by Consultants from Neighbouring Towns; (24) March 14th, 1896, Medical Aid Societies in Small Heath; Medical Clubs at Stockport; (25) March 21st, 1896, General Meeting of the Profession and the Formation of a Union at Nottingham; (26) April 4th, 1896, Nottingham; the London and Manchester Industrial Assurance Company, Limited; the Public-house Medical Aid Clubs; United Action at Lincoln; (27) April 11th, 1896, Leicester and Wolverhampton; a Hastings Dispensary wound up; (28) April 25th, 1896, Walsall, Formation of a Medical Union; the Medical Profession and the Friendly Societies; Trade and Medicine; the Family Clubs; Women's Public-house Clubs.

Digitized by Google

clothes, but his medical attendant, though not nearly so wealthy, was compelled to live in an expensive villa, keep a carriage, and wear a frock-coat and tall hat. This wealthy working man would have thought himself badly used if his club medical attendant had come to see him on foot and had been shabbily dressed. He would not have had confidence, and would probably hesitate to take the medicine sent. Several members of the friendly societies are tradesmen, and this is notably the case with regard to the Druids, one of the latter being a cab proprietor. Even the secretaries of the clubs are beginning to see that the pay given to the medical officers is insufficient, and, to judge from the remarks made, some slight increase might be obtained from several of the societies; but the necessity of imposing a wage limit is far more important.

Several practitioners complained of the habit very prevalent at Sheffield of changing medical men. During the healthy and active part of a man's life he will live near to his work, and but rarely requires the services of his club medical officer. But when he becomes old and his health begins to give way he will probably go and live in the outskirts of the town, and then will want to have his name transferred to the list of some other officer living nearer his new abode. Thus some club medical officers get an altogether unfair proportion of invalid members on their list. It has been urged that when a member of a club wants to make this change he should be examined by the new medical attendant and accepted by the latter only if he is in a healthy condition. This suggestion is perhaps not very practical, for it would place members of the clubs at a very great disadvantage when they want to remove. Still, from the practitioner's point of view it does not seem fair that one medical officer should have the majority of his club members aged from twenty to fifty years, while in a suburban district there should be an extraordinary proportion of club members who are more than fifty years old. It is very certain that the suburban practitioner will have much more work to do for the same pay, and this will be spread over a much larger space. In the present state of affairs it is difficult to see how this problem can be solved satisfactorily for both parties, but the grievance would disappear naturally and without effort if a wage limit was established. Those club members who are able in more advanced years to remove from the centre of the town to the suburbs are in many instances members whose financial circumstances have so improved that the application of a wage limit would remove them altogether from club practice. They would go to increase the private practice of suburban medical men. This would be so advantageous to the suburban practitioners as to constitute an ample compensation for the few club members who, though removing to the suburbs, might still be so poor as to justify their remaining in their clubs.

To deal with these questions a medical union must be formed at Sheffield. The profession needs protection against the touting extensively organised by the life assurance companies. Then the medical men who accept fees of 6*d*. and 1*s*. constitute also a great grievance.

Such methods of practice will, however, under the stress of competition continue and increase if a strong medical union is not formed to deal with all such questions. Some efforts have already been made to constitute such a union. The Sheffield Medico-Chirurgical Society has been asked to take the initiative and convoke a meeting so as to form a union. The reply was that every possible help would be given, but that the club medical officers and those who were themselves the principal sufferers should take the initiative in convoking the meeting; the leaders of the profession were, however, ready to associate themselves with the movement, to speak at the meeting, and in any other way help the cause forward. It may be said, therefore, that there is a general awakening at Sheffield and that the time is not far distant when this town will join with its neighbours in seeking to constitute a local union.

THE BATTLE OF THE CLUBS AT LINCOLN.

IN THE LANCET of April 4th we published a resolution and scale of fees which had been adopted by the profession in Lincoln as those which ought to rule in medical clubs. This document was duly forwarded to the two medical institutes. Replies have been received as follows:—

(1)

Oddfellows' Medical Institute, Unity-square, Lincoln.
April 11th, 1896.

DEAR SIR,—I am directed by the committee of the above Institute to forward you copy of resolution passed by them at a special meeting held last night.

Yours truly,
WM. COULSON, Secretary.

"This committee, having received a letter from the medical practitioners of Lincoln containing certain resolutions which they assert should be the future condition of membership of this institution, resolved—'That we hereby refuse either to accept the conditions or to recognise their right to dictate them.'"

(2)

Lincoln United Friendly Societies Dispensary,
April 17th, 1896.

DEAR SIR,—I am requested to forward to you the following resolution which was passed by the delegates of the two Medical Aid Associations of Lincoln at their meeting last evening.—Yours truly,
WM. BAVIN.

Resolved: "That this meeting, having considered the character and effect of the resolutions therein, hereby declares its inability to recognise in any way the manifesto of the medical men of Lincoln or any outside pressure attempted to be put upon the committee of Friendly Societies."

It will be noted that Messrs. Coulson and Bavin do not err upon the side of courtesy. As a consequence of these replies the following letter of resignation was sent in and signed by three of the four medical men attached to the institutions in question:—

LETTER OF RESIGNATION.

We regret your refusal to accept the principles put forward in the resolutions passed at the meeting of practitioners held on March 30th last.

Under these circumstances we are pledged to tender our resignation, which we beg you to accept for this day month, unless in the meanwhile you should agree to alterations on those lines which have been submitted to you.

April 22nd, 1896.

It will be noticed that we say this letter was signed by three out of four medical men. The fourth, although his name appears in the manifesto published in our columns of April 4th; although he signed an agreement dated March 28th pledging himself to act in unity with his colleagues: although he denied at a meeting held upon April 11th that he was not acting in unity with his professional brethren, and although he expressed no ill-will towards the gentlemen who had questioned his position but shook hands with him—yet, in face of all this, he has declined to send in his resignation with the others. He still holds his post. We hope that Mr. P. W. Young will see the curious position in which he stands—that of a nominal friend and virtual foe. We appeal to him to fall into line with his colleagues. His present course will do him no good whatever, though it may temporarily impede the course of justice to his professional brethren.

We congratulate the three medical men on their very proper stand against the arbitrary conduct of the medical institutes. They have acted for the good of the profession.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester and Salford Sewage.

THE adjourned case of the Mersey and Irwell Joint Committee against the Salford corporation for polluting the Ship Canal came before the Salford County-court on the 20th ult. The counsel for the corporation said the system for treating the sewage had been decided on, and application had been made to the Local Government Board to borrow £50,000 to carry out the works and to hold an inquiry at the earliest possible date in order that the necessary sanction may be obtained, so that the work proposed may be begun without delay. The case was adjourned till the result of the application to the Local Government Board—a body not always very speedy in its proceedings—was known. At the meeting of the Joint Committee yesterday Mr. R. A. Tatton, the chief inspector, reported as regards the treatment of Manchester sewage that since the last adjournment thirty acres of land have been brought into operation as a filtration area, but the amount of sewage dealt with by this area is only about 2,000,000 gallons per day out of a total dry weather flow of 14,000,000 gallons, the remainder being treated by precipitation only. It is expected that "the whole of the sewage will be connected up towards the end of the summer of this year." Sir Henry Roscoe, speaking after a report respecting certain analyses of effluents had been read, stated that experience showed that mere chemical precipitation—whether at such works as those of fellmongers, breweries, tanneries, or in the case of the sewage of a large town—would not do, and they must have either land filtration or artificial filtration.

Digitized by Google

He was glad to find that the chemical sub-committee had appointed a deputation to interview a number of fellmongers with regard to the serious pollution arising from their works, and to consider and advise as to the most satisfactory methods of dealing with the effluents from these places. A member of the committee said the condition of the Irwell had considerably improved, and Alderman Hopkinson was told that fish were coming up the Ship Canal as far as Latchford.

Special Treatment for Aged Poor.

The Manchester board of guardians deserve credit for endeavouring to treat those in their charge with humanity and discrimination. At the meeting a fortnight since Alderman McDougall moved a resolution to the effect that a committee should "consider and report as to the desirability and method of providing special accommodation and treatment for deserving aged persons; that until the method is decided upon and has been in operation for some time the selection should be made from inmates of the Crumpsall Workhouse; and that in considering such arrangements ordinary clothes should be provided and, if possible, periods of daily liberty be granted." The wording seems a little involved, but the intention is obvious, and if properly safeguarded the scheme would do much to brighten the closing days of many whose lines have been none too prosperous.

Hospital Saturday.

In a letter to the local papers Mr. Fred. Scott, the secretary to the Manchester Hospital Sunday and Saturday Fund and the Red Cross Society, corrects an impression likely to have an injurious effect. A delegate from a local town stated that in his district it was thought that the collections benefited only one or two of the principal hospitals in Manchester and Salford. Instead of this being the case "no less than twenty-one hospitals and other medical charities share in the proceeds of these collections, including hospitals for the treatment of special complaints, such as the Royal Eye Hospital, the Hospitals for Consumption and Skin Diseases, the Ear Institution, St. Mary's, Southern and Clinical Hospitals, the Cancer Pavilion, and other institutions at which large numbers of patients from surrounding towns are treated as freely as residents in Manchester and Salford." He appeals, therefore, to those living in the numerous towns in the surrounding district to support Manchester and Salford hospitals. The Red Cross Society is the working men's auxiliary to the Hospital Saturday and Sunday Fund. It has taken up the work of increasing the funds of the medical charities enthusiastically and hopes to effect a large increase in the sum contributed on Hospital Saturday, the arrangements for which day are under the special control of this new organisation.

Dog Muzzling.

For a long time past a good deal of feeling and irritation has been shown in this neighbourhood both by frequent letters to the papers and otherwise with regard to the sometimes apparently arbitrary enforcement of the muzzling order in certain districts, while in adjoining districts the dogs run free. If the muzzling were efficient, if it were carried out over the whole island for a period long enough to cover any possible length of incubation, and if the importation of dogs were absolutely prevented, there would be some compliance with common-sense requirements. But with the various ingenious devices adopted by many owners for preventing the efficiency of the muzzle and the frequent accident of the muzzle getting loose protection cannot always be relied upon. This partial enforcement is obviously irrational, for a mad dog often travels far and does not respect artificial boundaries, and it is no doubt felt to be so both by the muzzled and the unmuzzled dog when these sensible creatures meet on the imaginary line dividing the districts, the one to complain to, and the other to commiserate with, his friend. In a report of the Watch Committee of the Manchester City Council it is stated that under the muzzling order of February, 1895, 1008 summonses were issued against owners of dogs, 944 of whom were fined and 64 cases discharged. Most of these summonses were for dogs running out into the road unmuzzled, a thing difficult to prevent if they are to be allowed any freedom at all. But apart from the muzzling order an important and valuable work has been carried out systematically by the police in the impounding and destruction of ownerless and worthless dogs and the preservation and restoration of lost dogs to their owners. During last year 3331 stray dogs were brought by the police to the city pound and 598 by the owners. Of this total of 3929 219 were claimed, 253 were sold, 3439 were drowned, and 18 were waiting events. In January and February of this year 168 were brought by their owners to be destroyed for old age, disease, or savage and uncertain temper, and altogether more than 500 were impounded. There is usually a greater demand for the purchase of good dogs at the pound than can be met. They are sold at 2*s.* 6*d.* each, the purchaser giving an undertaking to restore to the owner, if required, on payment of the purchaser's expenses. The Watch Committee, after considering the subject, recommend: "(1) That the muzzling of dogs should be continued, subject to its being relaxed or dispensed with in the case of a dog which wears a collar with the owner's name and address and an official tablet, and is registered at one of the divisional police-stations; (2) that the existing muzzling order should be amended accordingly; (3) that the existing exemption in favour of sporting dogs be removed; (4) that all dogs be muzzled which are not registered and do not wear name-collars and tablets; and (5) that all dogs which do not comply with the regulation shall be destroyed or sold if not claimed within three days where the owner is not known, or within two, after notice, where the owner is known." There may be some difficulty about No. 3, and No. 5 implies a freedom of volition and throws on the dog a responsibility which the Watch Committee in its wisdom perhaps scarcely intended. If, however, this system of registration and supervision were universally carried out, and all stray dogs were impounded and, if need be, destroyed, cases of rabies would be less frequent and sooner detected, with a corresponding increase in the protection of the people against a frightful danger.

May 5th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Convocation of the University of Durham at Newcastle-upon-Tyne.

A CONVOCATION of the University of Durham was held in Newcastle-upon-Tyne on Saturday, April 25th. The ceremony took place in the library of the College of Medicine, and the Warden of the University, Dean Kitchen, presided. Honorary degrees were conferred upon the Lord Bishop of Newcastle, Dean Lukins Baronian, the Rev. Dr. Dallinger, Professor Arnison, Principal Gurney, Mr. Richard Howse, and Sir David Dale, Bart. Dr. David B. Lees, of St. Mary's Hospital, London, was admitted *ad eundem* M.D., and the Vicar of Newcastle, the Rev. Canon Lister, and the Rev. Canon Pennyfather *ad eundem* M.A. Some fifty ordinary degrees in medicine and surgery were also conferred. Great public interest was taken in this the first convocation held in Newcastle-upon-Tyne. The mayor and corporation attended in state and the large room was crowded with spectators. The undergraduates were, as usual, very much in evidence. The day was beautifully fine and the proceedings—owing in no small degree to the energy of Professor R. Howden, who is practically the dean of the Medical Faculty—passed off most satisfactorily.

The Bishop of Newcastle.

The Bishop of Newcastle preached last Sunday in the chapel of the Royal Infirmary to the inmates of the institution. Dr. Jacobs has not been long in the north, but he has on many occasions already shown his sympathy with the medical profession and the work of the medical charities of the city. He took a very active interest in the management of the hospital at Portsmouth, and it is to be hoped an opportunity will soon be afforded him of becoming connected with the Royal Infirmary here.

Typhoid Fever from Eating Raw Mussels.

In the River Blyth there are mussel-beds which supply a cheap and much-appreciated luxury to the poorer inhabitants of the populous town of Blyth. Unfortunately, close to them several sewers discharge their contents into the river. The medical officers of Bedlington and Cowpen report that the eating of mussels from these beds is a possible source of typhoid fever in the neighbourhood and the Board of Trade was approached upon the subject. Thence it was referred to the Sea Fisheries Committee for Northumberland and dismissed without remark. The Blyth port sanitary authority, on the

Digitized by Google

advice of its medical officer, who was of opinion no infection could arise on account of the process to which the sewage was subjected, will take no action. Mr. Laing, in his annual report to the Cowpen council, declares emphatically that he has traced some of the cases of typhoid fever to the eating of uncooked mussels and urges the destruction of the mussel beds. Mr. Laing's statement deserves careful consideration and ought to be thoroughly considered and the issue should be determined. It should not be a matter of indifference as to whether typhoid fever is being spread or not by the eating of mussels rendered unwholesome by sewage.

Stoppage of the Rainton Pits.

Work has now ceased at these pits and the men's gear and the horses have been withdrawn. Notice has been given to the pitmen that they must either pay rent or vacate their houses on May 13th. They profess to think this very hard, and at a recent meeting it was stated by one of them that he believed Lord Londonderry would rather pay six or nine months' rent for them than evict them, though his doing so would cause him to lose another £1000. Last year Lord Londonderry lost some £15,000 by working these collieries. At Seaton Delaval, a pit village in Northumberland, a coöperative store last year made only 15 per cent. and in consequence the wages of the employés have been reduced. The store is owned by workmen, the Rainton pits by a nobleman. We are told that coöperation will solve the difficulties between capital and labour. No one suffers more from the unfortunate disputes between capital and labour than members of the medical profession, who, when a pit is stopped or a strike takes place, have to work without remuneration and are often, if not ruined, seriously crippled for years.

Newcastle-upon-Tyne, May 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Lay Press and the Midlothian Medical Officer of Health.

THE official reports of a public servant are, of course, open to public criticism, and the reports of medical officers of health need have no exemption claimed for them even from the lay press. It is, however, highly desirable that when the lay press criticises it should do so through a person acquainted with the present state of knowledge on sanitary matters. The neglect of this precaution is detrimental to the public interest, because erroneous views on matters seriously affecting the public health are thereby promulgated or confirmed. The medical officer of health for Midlothian and the adjoining counties, Dr. W. J. Brock, in his annual report refers to several matters of great importance from the public health standpoint. He refers to the inefficiency of the chemical analysis of drinking water and says it is "*practically* of little use" as it is powerless to detect the germs of disease which the water may contain. He also refers to the town refuse traffic being a source of much annoyance and adds: "Although the city refuse is not supposed to contain human excreta a certain amount is always present. It, however, contains dust from the skins of those affected with scarlet fever and dried sputa from the respiratory tracts of those affected with diphtheria, measles, and tuberculosis; and it is not surprising that on its coming to a district there at once is found an unusual number of sore-throats if not one or other of the diseases mentioned. Is it not, too, a very likely means of spreading tubercular disease, not only to man, but to the lower animals?" At another part of his report, in referring to an outbreak of typhoid fever the source of which could not be discovered, he says, "There is a cause always to be thought of—namely, importation of infection through goods, such as aerated waters, greengroceries, &c." All these are propositions accepted by the scientific sanitarian, and it is most desirable that the public mind should be impressed with their accuracy and that the hands of the public health medical officers should be upheld in their endeavours to make them known to local authorities and to the general public. And yet while this is so we regret to see an Edinburgh newspaper, ever active to expose what may interest the public, adversely criticising these statements and making comments upon them which certainly convey to the public the impression that the medical officer of health is wrong and the writer of the article referred to right. The state of the writer's knowledge may be judged by the following: "The best medical, veterinary, and sanitary authorities are agreed that the germs of phthisis do not retain their vitality for many seconds after exposure to air and particularly to sunlight." There might be no objection to the writer of this believing that which he writes, but it is to be regretted that such erroneous doctrines should be thrown broadcast amongst a community. The efforts of sanitarians and physicians to get the public to realise the danger of dried tuberculous sputum is much counteracted by ill-informed statements of this nature in the lay press, and we regret when a newspaper is led by any of its contributors into such a false position as the above quotation indicates. It is out of place here to examine at length the objectionable article, for its value can be estimated by the above quotation. We may, however, add that the statements and views of the medical officer are by no means "remarkable" in the sense meant by his critic, but are the accepted doctrines of enlightened sanitation.

Glasgow Medico-Chirurgical Society.

This society met on the 1st inst., Dr. Walker Downie being in the chair. Dr. T. K. Dalziel showed a child aged three years the subject of Spina Bifida. At three months the tumour was injected with Morton's fluid, and in time its cystic character completely disappeared, leaving a firm, shrunken mass. Evidences of involvement of nerve became increasingly conspicuous. Paralysis of the lower limbs appeared, with loss of control over the bladder and rectum and ulceration extending deeply into each ischio-rectal fossa. It was, therefore, decided to cut down on the tumour with a view to see if the nerves could be freed from pressure. After removing a superficial mass of fibrous and fatty tissue the membranes were opened and the nerve roots were found to be involved in a quantity of cicatricial tissue. To remove this it was necessary to divide the nerve roots in the cauda equina and the divided ends of the roots were afterwards stitched. No ill results followed the operation except a high temperature which lasted only a few hours. For some time no improvement was produced, but latterly the efficiency of the bladder had increased, the ulcers had healed, and there was a favourable movement in respect of the paralysis. Dr. Stirton read a paper on Vaginal *versus* Abdominal Surgery in the treatment of various pelvic conditions. He contended that a number of diseased conditions in which it was the custom to open the abdomen could be far more safely attacked through the vagina, and he quoted in support of his position records from his wards in the Royal Infirmary in which he had successfully treated by puncture from the vagina cases of pyosalpinx, hæmatocele, extra-uterine pregnancy, and cysts of the broad ligament. The paper led to a somewhat animated discussion, in which Dr. Samuel Sloan, Dr. Edgar, Dr. Renton, and Dr. Rutherfurd took part. The latter questioned very decidedly the wisdom of puncturing a parovarian cyst without subsequent removal of the cyst wall. Dr. T. K. Monro showed photographs illustrating the Value of the Thyroid Treatment in cases of Myxœdema. Dr. Henry Rutherfurd showed two series of photographs illustrating Arrested Development of Bone. In one the arrest of development was due to acute arthritis (epiphysitis) occurring in infancy; in the other it was associated with cartilaginous tumours.

The Antitoxin Treatment of Diphtheria in Glasgow.

In the current number of the *Glasgow Medical Journal* Dr. Ernest L. Marsh publishes an elaborate series of statistical tables showing the influence of the antitoxin treatment on the cases of diphtheria admitted to the City of Glasgow Fever Hospital during 1895. The admissions numbered 179, and of these 137 were treated by antitoxic serum, the remaining 42 being either mild infections (38 cases) or profound toxæmias (4 cases) moribund on admission. The fatal cases numbered 25, giving on the admissions a percentage of 14 deaths. In the five years previous to 1895 the cases of diphtheria had never given a less percentage than 35·5 deaths in any one year, so that the improvement is a very impressive one. Of the 179 patients in 1895 tracheotomy was needed in 29, and of these 10 died, giving a mortality of 34·5 per cent. Dr. Marsh draws special attention to these cases and contrasts the low death-rate with the high mortality of the tracheotomy cases in previous years—viz., 76 2 per cent. (42 cases) in 1893 and 86·9 per

Digitized by Google

cent. (23 cases) in 1894. The article is a most complete one and is undoubtedly a very valuable contribution to the subject.

May 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Muzzling of Dogs in Dublin.

A RABIES scare exists in Dublin as elsewhere and is just now a subject of much interesting controversy. As regards the muzzling regulation, which has now been adopted by over eighty of the local country authorities in Ireland, the greatest difference of opinion prevails in Dublin. The South Dublin Union has approved of it and it is now enforced in that district, while the guardians of the North Dublin Union hold, "more Hibernico," a different view. The consequence is that it is not uncommon to see owners of dogs removing their muzzles as they cross over Carlisle bridge. Dr. Henry Fitzgibbon attended a recent meeting of the Guardians of the South Dublin Union and protested strongly against the muzzling of dogs as being calculated to produce rabies and to develop in rabid dogs a biting tendency. He failed, however, to have the order rescinded, although he utilised more than a column of the *Irish Times* in putting forward his views, which, as he is known to be a philanthropist and sportsman as well as a surgeon, carry a good deal of weight. "No muzzle," he says, "has yet been invented which is really effectual, and wire muzzles can all be dragged off by a dog's claws unless the strap round the animal's neck is almost tight enough to choke him." Dr. Fitzgibbon says, further, that this fact is so well known to dog owners that they do not attempt to really muzzle their dogs, but merely apply an ornamental contrivance to satisfy the police. A real muzzle is, moreover, in his opinion, a cause of madness, rabies sometimes originating without contact with another diseased animal. He gives three very interesting instances in support of this statement from his own experience, and concludes by strongly advocating the careful registration of all dogs, and obliging each of them to wear and be distinguished by a collar with a number attached. It is satisfactory to note from a statement of Mr. Gerald Balfour in the House of Commons last week that a Departmental Committee of the Board of Agriculture is being appointed to inquire into the working of the laws relating to dogs, and that the Irish Veterinary Department would be represented on it.

Royal College of Surgeons in Ireland.

The vacancy in the College Council was filled on the 4th inst. by the election of Dr. J. J. Cranny. The examining courts for the next year have just been elected.

Londonderry Eye, Ear, and Throat Hospital.

On April 28th the Lord Bishop of Derry and Raphoe opened a new Eye, Ear, and Throat Hospital for Londonderry and the north-west portions of Ireland. For some time Mr. Donaldson and other medical men have carried on this special work in premises in Hawkin-street, but as these buildings were hampered it was decided to provide a new building, which is situated in Rudge-street. This new hospital contains patients' waiting-rooms, consulting-rooms specially designed for the testing of sight, caretaker's room, and kitchen, all on the ground floor. Overhead are the operating-room and the two main wards—male and female—each capable of accommodating six beds. The nurses' rooms are on the top floor. Special lavatory fittings have been placed in the operating-rooms, and altogether the new hospital is in every respect most complete and commodious.

Epidemic of Measles in Newtownards.

At present there is an epidemic of measles in Newtownards. The matter came before the School Attendance Committee at their meeting on April 30th, and it was reported that the sanitary officer had gone to the houses where the disease exists and warned the people not to send their children to school. It was decided not to close the schools yet.

Local Government Board Inquiry at Downpatrick.

At a meeting of the Downpatrick board of guardians held on May 2nd a report was read from the Local Government Board in reference to the inquiry recently held by their inspector, Dr. Clibborn, into the circumstances attending the death of a dispensary patient in Downpatrick during the time the medical officer was required at the Down Assizes. The Local Government Board think the medical officer showed a want of consideration in the case that was not creditable to him, and while he no doubt complied with the regulations, yet his action in not visiting the sick man was to be disapproved of, although it was probable medical assistance would not have availed in the case. They held that the relieving officer deserved censure for not attending at the dispensary on March 13th as directed by the medical officer, and they had caused the facts elicited at the inquiry to be noted against him in the records of the office. The Local Government Board added it was much to be regretted that the guardians did not formally sanction the arrangements proposed to be made as to a medical substitute during the absence of their medical officer.

May 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Strange Endemic.

A CURIOUS incident, which occasioned considerable disquietude amongst the inhabitants, occurred recently at Barfleur (Manche). A young girl, a native of Barfleur, came on a visit to her parents from Cherbourg, where she was in service. During her stay at home she consulted a medical man with a view of ridding herself of a parasite which she had brought from Cherbourg, and which, having multiplied with prodigious rapidity, had infested the house of the patient's parents and also that of a relative. Sulphur was burnt in the house, and the linen and flooring were washed with sublimate solution. The plague continuing with undiminished intensity the neighbours ceased visiting the infected houses and sent the denizens thereof "to Coventry." The authorities then took the matter in hand and delegated M. Edmond Perrier, Member of the Institute and Professor at the Museum of Natural History of Paris, to investigate this mysterious malady. He soon discovered that the *origo mali* was the Glyciphagus domesticus, an acarus closely allied to the acarus scabiei, but, unlike the latter, provoking scarcely any itching or cutaneous lesions in its hosts. This acarus is, it appears, very commonly present in houses, and it is frequently met with in the interstices of hair-combs which are badly kept. It multiplies especially in houses in which organic débris accumulate. In groceries an acarus, the Glyciphagus prunorum, which is perhaps identical with the Glyciphagus domesticus, often flourishes on dried fruits, such as prunes and figs. Feeding exclusively on organic matter it is only a pseudo-parasite. Besides the Glyciphagus domesticus there was discovered in these same contaminated houses at Barfleur a false scorpion, the othonius, which had invaded them in the train of the first-named parasite. The othonius, otherwise called the *pince des bibliothèques*, is the declared enemy of the Glyciphagus domesticus, upon which it feeds exclusively. Three millimetres long, and resembling a tailless scorpion, it is recognisable by its long fore-claws shaped liked the lobster's. The young Barfleuraise had at Cherbourg been a servant at a pork-butcher's, and it was probably at the *charcuterie* that she became infected. Her scalp was so full of acari that when she shook her head a cloud of them fell on her shoulders. Her father, a respectable fisherman, had his eyebrows attacked, the only symptom being a slight irritation. A garment left by the girl at an aunt's had sufficed to infect an exceptionally clean house. M. Perrier ordered the evacuation of the houses and sulphur to be burnt during six hours in the sealed-up rooms, with the result of killing every acarus, as also the othonius. An eau de Cologne and sublimate lotion relieved the persons of the sufferers of the parasite, although the treatment had to be prolonged in the case of the girl. The case is interesting in that the acarus, caught at a pork-butcher's, had lain dormant for some time on the hair-comb, and transferred thence to the scalp had thriven therein for a period of eighteen months and invaded consecutively the garments. From the garments the parasite had spread to two houses and their inhabitants and the othonius had promptly followed in pursuit.

The Prophylactic Employment of Marmorek's Serum before Cataract Extraction in Diabetics.

M. Boucheron[1] had recently under his care a man aged seventy years who, passing 46 grammes of sugar per litre of urine, was affected with a streptococcic disease—lymphangitis of the foot and leg. At M. Marmorek's suggestion 20 grammes of his anti-streptococcic serum were injected. Taking advantage of the consequent attenuation of the vitality of the streptococcus a cataract was extracted, strict antisepsis being, of course, observed. The corneal wound healed by first intention and the lymphangitis soon disappeared. This preventive treatment may prove useful previously to operation on a diabetic patient in whom suppurative processes due to streptococcic invasion are very prone to occur.

The Campaign against Foreign Medical Men.

The *Médecine Moderne* of May 2nd informs us that the *internes* in medicine and surgery of the Paris hospitals have almost unanimously—218 "yeas" against 11 "noes"—signed the following petition: "1. Any foreigner may be allowed to enter (*prendre ses inscriptions*) in a French faculty of medicine, but the degree of M.D. can only be accorded him *à titre d'étranger*, without conferring any right to practise in France. 2. No foreigner can practise in France unless he be naturalised a Frenchman, have performed military service in the French army, and be provided with the degree of *bachelier*." When we consider that a French M.D. is allowed to practise his art unmolested in our own free England we cannot but wonder that educated young men—the cream of the French *jeunesse médicale*—should lend themselves to the propagation of such illiberal proposals. I wonder what comment landlords of hotels and boarding houses and the tradesmen in general of French health resorts will make on a petition the application of which would hardly be favourable to their interests. We may perhaps treat the above move as the outcome of youthful exuberance, but that a strong anti-foreign current has set in amongst members of the profession in this country is a melancholy fact. Were our French *confrères* more frequent visitors to England they would learn that the travelling Briton prefers, rightly or wrongly, to be attended in case of illness by an English physician, and he would then not allow his common sense to be over-ruled by arguments dictated by his supposed commercial interests. The English practitioners who would renounce their nationality for the sake of being allowed to practise in France are, I am sure, in a hopeless minority. The adoption of protectionist measures could therefore only have the effect of stemming the tide of English visitors to French health stations. The Frenchman who cannot be accused of indifference to his pecuniary interests would then claim loudly a return to the present *régime*, which is in accordance with the liberal principles that should prevail in every civilised country.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Serum Treatment of Scarlet Fever.

A PAPER on the Treatment of Scarlet Fever by Dr. Marmorek's Anti-streptococcic Serum has been read before the Berlin Medical Society by Professor Baginsky, who said that streptococci are often found in scarlet fever, especially in complications and in the septic form of the disease. Dr. Marmorek has not discovered the specific antitoxin for scarlet fever, but he has found that the serum of animals immunised in the usual way by virulent cultures of streptococci has immunising effects on animals submitted to experiment and a beneficial influence in streptococcic diseases, such as erysipelas and cellulitis. It is inoperative against the special virus of scarlet fever, but Dr. Marmorek believes that it is useful in the streptococcic complications of that disease, if given in repeated and sufficiently large doses till the temperature becomes normal. He has in Paris used this treatment for ninety-six cases of scarlet fever in which streptococci were found. Loeffler's bacillus being also present in seventeen of them. The first injections for the children were 10 c.c., but the quantity was afterwards raised to 40 and 80 c.c.; in one instance of pneumonia as much as 90 c.c. (equal to 3¼ fluid ounces) were successfully given. The antitoxin had a specially favourable influence on inflamed lymphatic glands, otitis, and tonsillitis, suppuration being sometimes prevented. Professor Baginsky then gave an account of the results obtained by himself in the treatment of 57 cases of scarlet fever both with and without complications. Nine of those cases ought properly to be disregarded, partly because the treatment was interrupted by failure in the supply of serum and partly because the patients were actually moribund when the serum was used. The other forty-eight cases may be divided into three groups. In the first, consisting of twenty-seven patients, the treatment was begun in the first stage of the illness, there was a rapid improvement after the injection of from 10 c.c. to 30 c.c., and no complications ensued. Professor Baginsky, however, remarked that mild cases are not rare, even in the absence of any treatment. In a second group the antitoxin was also administered from the beginning, but the results were much less satisfactory. Of sixteen patients six died with general sepsis or septic complications, and the remainder suffered from severe otitis, glandular suppuration, nephritis, &c. It is possible, however, that these unfavourable results may have been due to an insufficient quantity of serum having been used. In the third series, consisting of five cases, the antitoxin was administered, not from the beginning, but during the course of the illness. One of these patients died from otitis with thrombosis of the sinus, in another the submaxillary gland suppurated and had to be opened, while in the three remaining cases a favourable influence on the temperature was probable. Taking the whole series, there were seven deaths among forty-eight patients, or a mortality of 14·6 per cent., a relatively good result compared with the average mortality of this year's epidemic, which has been about 30 per cent. Professor Baginsky was of opinion that it would be premature to form a definite opinion as to the usefulness of the remedy, but that there is sufficient justification for giving it a trial.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Therapeutics of Cancer.

BEFORE the Associazione Medica Lombarda, in the presence of the leaders of the Milanese School, Dr. Jona read a paper the other evening on "Cura del Cancro." After a brief survey of the recent literature of the subject he subjected to a critical analysis the various attempts to utilise sero-therapy either by inoculating the patient with the toxine of erysipelas or by injecting the blood serum of animals prophylactically inoculated with liquid drawn from carcinomatous tumours. This latter method, according to the instructions laid down by Dr. Richet and Dr. Héricourt, was that adopted by Dr. Jona, who had under his care six persons suffering from that special form of malignant disease. One of these patients—a woman who for six or seven months had laboured under well-defined cancer—was manifestly relieved by the treatment; another—a man afflicted with cancer of the stomach and unable to digest or even tolerate food passed down the œsophagus—had no sooner begun the sero-therapy than he recovered the power of alimentation by the *primæ viæ*, digesting with perceptibly favourable results as many as twelve eggs daily. Two other patients—one suffering from cancer of the tongue and the other from cancer of the rectum—showed distinct improvement after the first injections; but the improvement was not maintained. The fifth and sixth cases, one of cancer of the tongue and the other of the inferior maxilla, remained without response to the treatment. Dr. Jona's paper was distinguished by much caution as well as thoroughness, its writer contenting himself with having made out a case for further experiments to be laid before the Associazione Medica Lombarda.

The Drainage of Milan.

Though the English-speaking residents in Milan are few the English-speaking visitors are very numerous—so numerous, indeed, as to make the sanitation of that mighty *entrepôt* of the Brindisi route a matter of very considerable importance, her water-supply is still defective and will remain so till she follows the example of Florence, of Naples, and, above all, of Rome, and replaces her wells sunk in the subsoil by fresh, pure water brought down in adequate volume

Digitized by Google

from the neighbouring hills. Her drainage is at present engaging municipal and, indeed, public attention, and no wonder, considering the quasi-mediæval system that has been allowed to vitiate her health so long. Her mortality in consequence reaches a figure discreditable to a city of her wealth and European importance. No doubt she has shared in some of the benefits of nineteenth century hygiene, and her death-rate is not what it was fifty years ago—viz., about 40 per cent. Still, a mortality ranging from 27 to 28 per cent., excluding the garrison, shows badly beside that of Zürich, for instance, with its 17 per cent., of Geneva with 19 per cent., of Frankfort with 20 per cent., of Lyons with 21 per cent., and of Brussels with 22 per cent. In these circumstances the proposals now before the civic authorities for relieving the population of its sewage on a comprehensive, systematic, and effective scale must be welcomed as a step all too tardily deferred, preceding efforts in the same direction dating as far back as 1866. Within the last seven years 4,966,000 francs have been expended in such drainage as already exists, but twice as much again will have to be laid out before Milan can be safe, not merely for her own inhabitants, but for the travelling public to which she owes not a little of her wealth.

May 4th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Alleged Fatal Injection of Diphtheria Antitoxin.

PROFESSOR PALTAUF has published in the *Klinische Wochenschrift* a highly interesting article showing that the *post hoc ergo propter hoc* argument has been greatly misapplied in connexion with the unfortunate incident in Berlin, when a child died almost immediately after receiving a hypodermic injection of diphtheria antitoxin. There is not as yet any proof that antitoxin serum possesses dangerous qualities, and, on the other hand, it is well known that in a great many cases of sudden death occurring both in children and adults post-mortem examination shows only insignificant lesions. In Vienna, where post-mortem examination is obligatory in every case of sudden death, some important observations have been made on this subject. For instance, Dr. A. Paltauf, brother of the writer of the above article, but now deceased, has pointed out in a pamphlet on the Relation between Sudden Death and the Thymus Gland that during 1887 there were 126 and during 1888 there were 99 deaths of children in Vienna in which post-mortem examination yielded no definite results, enlargements of the lymphatic glands and the spleen and paleness of the skin being the most conspicuous appearances. The late Professor Kundrat also observed these symptoms in rachitic children and believed that rachitis is not only an abnormality in the growth of the bones, but a general disturbance of the animal organism. The above symptoms have also been noticed in adults who have died whilst taking a bath, and therefore a so-called *status lymphaticus* has been suggested as the cause of death in these cases. Instances of death after the use of antitoxic serum have been quoted by Moizard, Quinon, and Alföldi, but none of the cases have been examined in such a manner as to prove the absence of any other disease. One of Alföldi's cases was a child who after having been immunised was allowed to sleep with his brother suffering from diphtheria and died in three days. Professor Paltauf's statistical returns show among 248 cases of prophylactic injection a sickness incidence of 6·85 per cent.—namely, angina in four instances, diphtheria with moderate local symptoms in nine cases, and severe diphtheria in four cases. It is well known that the injection may be followed by exanthemata, pains in the joints, and fever; but there is no case in which death has resulted from these sequelæ. Among 603 cases there were 44 examples of local erythema, 17 of general erythema, and 2 of rheumatic arthritis. The last symptom, which is also the gravest, occurred, therefore, in only 0·33 per cent., and notwithstanding these comparatively unimportant drawbacks there is no doubt that parents will continue to rely on antitoxic serum, by which the diphtheria mortality has been reduced from 40 per cent. to 14 per cent. The good effect of the serum treatment appears from the following statistics. In Vienna there were 1631 deaths from diphtheria in 1893, 1637 in 1894, and 690 in 1895 when the serum treatment came into use; in Trieste there were 394 deaths from diphtheria in 1894 and 272 in 1895; in Prague there were 193 deaths from diphtheria in 1894 and 83 in 1895; in Brünn there were 104 deaths from diphtheria in 1894 and 51 in 1895. In view of these results Professor Paltauf said that it is unjustifiable to condemn a recognised system of medical treatment and to create alarm in the minds of the public on account of a death the relation of which to the injection of antitoxin has not been ascertained. On the other hand, Professor Paltauf's statistics and his inferences therefrom have in the same journal been called in question by Professor Kassowitz, who asserts that the serum treatment was introduced in Trieste in 1894 and was employed in 362 cases from August to the end of the year. Furthermore, during the period from 1889 to 1893, both years inclusive, the annual deaths from diphtheria averaged 142, the actual numbers for each year being 98, 93, 118, 182, and 222, but there were 394 deaths in 1894 and 271 in 1895. Trieste, in fact, has a very high mortality from diphtheria as compared with other large towns, inasmuch as for each 10,000 of the population there died from diphtheria in Trieste 16·9; in London, 5·6; in Paris, 1·7; in Budapest, 4·2; in Munich, 5; in Leipzig, 4·5; and in Berlin, 5·3. In some towns, such as Paris and Budapest, the absolute mortality has decreased since the introduction of the serum treatment, but in London, although the diphtheria mortality was lower in 1895 than in 1893 and 1894, it was nevertheless very high in the last quarter of 1895, during which period there were 836 deaths from diphtheria, whereas there were only 469 in the same quarter of 1891, before serum treatment was in use. In Moscow and St. Petersburg the deaths from diphtheria have even increased, and Professor Kassowitz, therefore, believes that a decrease of diphtheria mortality is not attributable to the beneficial effect of antitoxin serum, neither does an increase in the mortality lead to the conclusion that the serum is injurious.

The Effect of Amyl Nitrite.

At a recent meeting of the Medical Society Dr. Winkler stated that a small quantity of amyl nitrite introduced into the respiratory organs of a narcotised dog produces a decrease of the pressure in the arteries and the characteristic symptoms of cardiac asthma—namely, dyspnœa, with accelerated and deep breathing and œdema of the lungs manifested by crepitant râles. Although the blood pressure is decreased in the arteries it is increased in the left auricle. The decrease of the blood pressure after the administration of amyl nitrite has hitherto been ascribed to its action as a vaso-dilator, but it obviously has an effect on the heart as well as on the vessels.

May 4th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Medical Department of the Egyptian Army.

IT is now five weeks since the English Government suddenly determined that the time had arrived for Egypt to extend her southern frontier and to embark upon an expedition of which neither the goal nor the cost has yet been foretold. It is greatly to the credit of the English officers forming the Headquarter Staff that without a hitch 15,000 men have now been massed between Wady Halfa and Akasheh. The only difficulty which has transpired so far is the impossibility of providing commissariat transport for men and animals without due preparation. Practically nothing can be bought on the spot, and consequently the men and horses at the advanced post have come very badly off for food. No serious forward movement can be attempted until the army is provided with at least two months' rations and forage, and this is not likely to take place for the next two months. Convoy duty under a broiling sun and working for thirteen hours a day on desert tracks so rough that only about eighteen miles can be traversed daily is the sort of work which has been uncomplainingly endured. Surgeon-Lieutenant-Colonel Gallwey, principal medical officer of the army, is still in Cairo making his final arrangements for the disposition of men and material, but he hopes now to join the Headquarter Staff at Wady Halfa. There are now seven British officers under him all lent by the English army and all of the rank of surgeon-captain. The two seniors have the Egyptian rank of *kaimakan* or lieutenant-colonel, and the

Digitized by Google

others are *bimbashi* or major. All medical officers hold military rank only like all other officers. Surgeon-Captain Hunter is the senior medical officer of the expeditionary force and is in charge of Wady Halfa Hospital, which may vary from 140 to 340 beds. Surgeon-Captain Penton is in charge of the Akasheh field hospital of 200 beds, with a section of a movable field hospital ready equipped to accompany any forward movement. Surgeon-Captain Trask is at Sarras with a ten-bed hospital and another movable field hospital. Surgeon-Captain Spong is sanitary inspector of the line of communication between Wady Halfa and Akasheh, and is responsible for all latrines and the conservancy of the various camps and drinking-water supplies. Surgeon-Captain Hill Smith is sanitary officer at Wady Halfa, Surgeon-Captain Whiston is at the general hospital in Cairo, and Surgeon-Lieutenant Dunn is at the Suakin permanent hospital. To work under the English medical officers there are fifty-five Egyptian medical men, two of whom have the rank of bimbashi. These natives get paid £12 a month on joining and this increases up to £35 a month. The following medical posts are now established south of Wady Halfa:—Gemai, Sarras, Railhead, Semneh, Mograt Wells, Wady Atireh, Ambigol (which also has a field hospital for 20 beds), Ambigol Wells, Tangoor, and Akasheh. North of Wady Halfa there are the two permanent hospitals at Assouan and Korosko. The slightly sick or wounded will be treated at the front and returned as rapidly as possible to the ranks, while the severe cases will be gradually evacuated until Cairo is reached. The non-commissioned officers and men of the medical service number 350, including 100 of the medical reserve who have just been called up. The Egyptian army is at all times the healthiest in the world, and the present rate of sick is under 3 per cent. When the regiments were ordered to the front there was no weeding out of weakly men, for all were kept ready for active physical work. This does not apply to the black battalions, where there were many older men engaged for life. Several small innovations are worth mentioning. A bearer company for 100 wounded has been attached to the sections of field hospitals, provided with camel cacolets specially designed by Dr. Graham Bey, who has lately been transferred from the army to the sanitary department. A small bearer company of ten mules will accompany cavalry and camelry. Cotton wool has been obtained from Germany so compressed that it takes up only half the bulk of the ordinary packets. Each English surgeon-captain will be provided with a medicine chest of compressed tabloid drugs similar to those in use on the Congo. Instruments and all appliances have been ordered from London of the newest approved aseptic patterns. Lastly, a six-bed hospital has been sent to Wady Halfa for the use of English officers, of whom there are now 110 serving on the Nile. The diseases most likely to be met with at this season are sunstroke, simple continued fever, diarrhœa, and dysentery.

Cholera at Alexandria.

During the month of March there were only nine cases of cholera reported with nine deaths. In fact, from March 12th to April 1st there was only one case, bulletins were discontinued, and it was quite hoped that the disease had come to an end. But during the first three weeks of April there have been cases almost daily, numbering altogether 45, and of these 42 have died. An English merchant has lately had a slight attack of cholera, but with very few exceptions the disease has from the beginning been confined to the poorest native quarters. Outside Alexandria there has only been one case and that was at Assiout in a man who had just arrived there from Alexandria.

Infectious Fevers.

During the last three weeks there have been 287 cases of small-pox and 54 deaths. The cases have been reported from thirty-four villages in Lower Egypt and about seven in Upper Egypt. During the same weeks there have been 229 cases of typhus fever and relapsing fever with 34 deaths, almost all being from fifteen villages in Lower Egypt. Measles in two villages and at Port Said has furnished 32 cases and 11 deaths.

Cairo, April 22nd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Conference on Federal Quarantine.

THE conference of medical representatives from the colonies of New South Wales, Victoria, South Australia, and Queensland, which was held in Melbourne from Feb. 28th to March 3rd to consider the subject of Quarantine, agreed upon certain resolutions of which the following is an abstract:—

1. That there be uniformity in the laws and practice relating to quarantine throughout the Australasian colonies; that the notification of all quarantinable diseases be made compulsory, and that each colony agree to have constantly in readiness accommodation for the isolation of persons who may be affected with any disease quarantinable in that colony, and to urge the removal of such persons from infected vessels.
2. That all ships coming into Australasian ports be liable to medical inspection for quarantine purposes.
3. That three fully qualified medical men, experts in the diagnosis and treatment of quarantinable diseases, be appointed as federal medical officers, devoting the whole of their time to the performance of their duties, and having their headquarters at Albany, Adelaide, and Thursday Island respectively, and, if found necessary at a later date, a fourth at Palmerston.
4. That a federal supply of calf vaccine lymph, sufficient for the vaccination of say 600 persons, be maintained at each of the ports of Albany, Adelaide, Thursday Island, Palmerston, and Colombo, such supply being available for the master of any vessel having a history of small-pox.

* * * * * * *

11. That every person who refuses vaccination be detained until the health authority is satisfied of the inability of such person to spread small-pox, but for no shorter period than twenty-one days.

* * * * * * *

14. That the method adopted by the health authority of Victoria in dealing with letters in quarantine be regarded as completely satisfactory—viz., the soaking of the written letters, enclosed in their envelopes and addressed, in a solution of corrosive sublimate in methylated spirit, of the strength of 1 part of the former to 100 of the latter, for a period of twenty minutes.
15. That all dogs imported into Australasia be subject to quarantine for a period of not less than six months, and that such quarantine be in every case performed in the Government quarantine ground only.

These recommendations were submitted to a conference of the Premiers of the respective colonies and were adopted with some modifications, such as that no ship should be relieved from the payment of quarantine expenses; that the experts to be appointed as federal quarantine officers should be at liberty to perform other public duties, that they should be nominated by the colonies in which they were to serve, and that their appointments should be approved by a majority of the contracting Governments. The proposal to hold another conference in twelve months was not adopted.

Disputes at the Adelaide Hospital.

Reference has previously been made to the unfortunate state of affairs at the Adelaide Hospital. The Government has now actually interfered, with very unsatisfactory results. It insisted on the re-instalment of one of the nurses who was one of the principals in the original dispute, and has appointed a new board of management, nominating thereon a practitioner who was removed some two years ago from the local branch of the British Medical Association for alleged unprofessional conduct. The Honorary Staff immediately resigned, as did two of the members of the board. The member to whom exception was taken then withdrew from the position, but the staff have not withdrawn their resignations, and so the matter stands.

Murderous Attack on a Medical Man.

Dr. Cunningham of Talbot, Victoria, has just been made the victim of a most violent attack by a supposed lunatic. On answering a night ring at his door he was felled by a blow from a tomahawk, and his assassin continued to batter his head with this implement. Mrs. Cunningham came to his rescue and drove off the would-be murderer with a pair of tongs. The doctor's skull is severely fractured, and his recovery is still doubtful. It appears that the assassin had his eye removed some years ago at a hospital and has ever since entertained feelings of animosity towards the medical profession. Great sympathy is felt for Dr. and Mrs. Cunningham who have been in the district for many years and are exceedingly popular.

The Toxic Action of the Secretion of the Femoral Gland of the Ornithorhynchus.

Some time ago reference was made to some cases supposed to be due to poisoning by the spur on the hind leg of a platypus or ornithorhynchus, and doubt was expressed as to whether the secretion of the femoral gland of this strange animal was toxic or not. In the recently published transactions of the Linnean Society of New South Wales is a paper on this subject by Dr. C. J. Martin and Mr. F. Tidswell. As a result of their investigations they find that the secretion is poisonous—at least at certain seasons of the year—and owes its toxic properties to proteid constituents in which it resembles the venom of snakes, causing like it intra-vascular clotting in large doses and retarding coagulation in small

Digitized by Google

doses. Like snake venom also it produces an almost instantaneous fall in the blood-pressure, capillary hæmorrhages, irritation, and œdema when locally applied, the local effects being more marked than in the case of snake venom.

Pharyngomycosis Leptothricialis.

In the March number of the *Australasian Medical Gazette* Dr. C. Purser records the case of a patient suffering from asthma and also from a sore-throat, the tonsil and mucous membrane below it being swollen and showing a number of white projections which gradually increased in number and size and were removed by curetting. The growths were found to contain an excessive number of the bacillus (leptothrix) buccalis maximus and the leptothrix innominata, and to their excess the condition is attributed.

Health of Melbourne.

The annual report of the medical officer of health for the city of Melbourne for 1895 shows that in general the health of the population has been good, the rate of mortality being 15·1 per 1000, an improvement on the two preceding years. Twenty deaths are ascribed to influenza, as against 8 in 1894. Tuberculosis caused 177 deaths, and the rate of mortality from epidemic disease was extremely low.

Obituary.

George Whitfield Sutherland, B.A. Syd., M.D. Lond., died at Sydney on March 3rd at the early age of thirty-two years. Dr. Sutherland had a most brilliant career as a student, but force of circumstances drove him into a very large lodge practice in Sydney, and to the strain and overwork attaching thereto his early death is mainly attributable.—Charles McCarthy, M.D. Melb., L.F.P.S.G., died at Melbourne on Feb. 24th in his eighty-third year and after a residence of thirty-five years in the colony. He was well known as an authority on inebriety, having been for twenty years medical superintendent of the Northcote Inebriate Retreat, near Melbourne.

Hospital News, &c.

Dr. Cecil Purser has been appointed assistant physician to the Prince Alfred Hospital, Sydney, and Dr. W. H. Crago assistant surgeon to the Sydney Hospital. — Dr. J. R. MacQueeney and Dr. H. M. Maudsley have been appointed consulting physicians to St. Vincent's Hospital, Melbourne.—A new wing at the Eye and Ear Hospital, Melbourne, was recently opened by his Excellency Lord Brassey. The wing is called the Aubrey Bowen wing, in memory of the late Dr. Bowen, who was one of the founders of the hospital and one of its first surgeons, and to whose generosity the institution owes much. The new wing has been built by his widow, who has also built a new operating theatre for the Melbourne Hospital, which will be formally opened in a few weeks.—Dr. Fiaschi, one of the leading surgeons in Sydney, inspired by his patriotic feelings, has left for Abyssinia to serve as a volunteer in the Italian army. The honorary medical staff of the Sydney Hospital passed a unanimous resolution expressing its sense of loss sustained by Dr. Fiaschi's departure.—The committee of the Williamstown Hospital, near Melbourne, having investigated certain allegations made by one of the staff, have come to the conclusion that there is no ground for these allegations and have called upon the gentleman who made them to retract them or resign.

April 4th.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—ELECTION OF EXAMINERS.—The following have been elected examiners of the College:—Examiners in Anatomy: John Barton and Alexander Fraser. Examiners in Surgery: Arthur Chance and William Stoker. Examiners in Physiology and Histology: J. Alfred Scott and Charles Coppinger. Examiners in Biology: J. Alfred Scott and George Burbidge White. Examiners in Pathology: Thomas Myles and Edward H. Taylor. Examiner in Midwifery and Gynæcology: E. Winifred Dickson. Examiners in Ophthalmology: Patrick William Maxwell and John Benjamin Story. Examiners in Dental Surgery and Pathology: Arthur W. W. Baker and R. Theodore Stack. Examiners in Mechanical Dentistry: Shenstone J. Bishop and Charles Wall. Examiners in Chemistry and Physics: J. Dallas Pratt and Edwin Lapper. Examiner in Sanitary Law and Vital Statistics: D. Edgar Flinn. Examiner in Bacteriology: J. Alfred Scott. Examiner in Engineering and Architecture: J. Charles Wilmot. Examiner in Languages: Robert John Montgomery. Examiner in Mathematics, Physics, Dictation, and English Essay: Robert Morton.

Obituary.

WILLIAM LOCKHART, F.R.C.S. ENG.

WILLIAM LOCKHART, who was so well known as a medical missionary in the far East, and whose name is associated with some of the most stirring incidents in the history of our relations with China, passed away on the morning of April 29th at his residence at Blackheath at the ripe age of eighty-four years. Up to the end of the previous week he was full of vigour and in the enjoyment of all his faculties, but on Monday, April 27th, he had a severe attack of vomiting and was found to be suffering from obstruction of the bowel. At a consultation held that night it was found that, owing to his advanced age and the state of the pulse, all operation was out of the question, and he soon afterwards became unconscious and passed peacefully away without any suffering. Mr. Lockhart pursued his medical studies at Guy's Hospital and the Meath Hospital, Dublin, and became a Member of the Royal College of Surgeons of England in 1834 (he was elected to the Fellowship in 1857). He first began practice as assistant to Mr. Wainwright of Liverpool, where he remained for three years, but on the return of John Williams and Dr. Moffat from their missionary journeys he was fired with the desire of becoming a medical missionary and offered his services to the London Missionary Society in that capacity. He was appointed to China, and left England with Mr. (afterwards Dr.) Medhurst, then engaged as a missionary to the Chinese in Batavia. Mr. Lockhart began his work at Macao in 1839, Dr. Parker, an American, having already obtained a footing as a medical missionary at Canton. From Macao he moved to Chusan on its first occupation by the British, and as soon as Shanghai was opened up, in 1843, he moved on to that city and founded a hospital there which was most successful from the first, the Chinese patients soon reaching the large number of 10,000 in ten months. Mr. Lockhart remained there until 1858, and during the Tai-Ping Rebellion, when the rebels had taken possession of the city, which was invested by the Imperial troops, his hospital, which stood in an isolated position outside the city walls, lay between the two contending armies exposed to the fire from both sides. Under these trying conditions he steadily pursued his work among the sick and wounded, the shells on several occasions bursting within the building. The last shell which entered the hospital burst upon the floor of the hall crowded with patients, on the very spot from which only a few moments before a wounded patient had been removed. The French troops having joined the Imperialists, Mr. Lockhart volunteered for the perilous errand of entering the city in order to try to persuade the rebels to surrender. In company with his friend Mr. Wylie he safely passed the rebel outposts, and for several hours used his endeavours to induce them to surrender to avoid further bloodshed. The commanders, however, while listening to his proposals, declined to yield the city, which they afterwards evacuated and burned. Mr. Lockhart always described this burning of the city of Shanghai as the most impressive sight he had ever seen. He returned to England in 1858 leaving the hospital under efficient superintendence for the further extension of its sphere of usefulness, and he had the satisfaction of knowing that it is at the present time the most important hospital for Chinese in China; the early picturesque Chinese structure has been replaced by a very substantial modern building with a hundred beds and a large out-patient department.

During his short stay in England stirring events again took place in China. Mr. Lockhart's brother-in-law, Mr. Parkes (afterwards Sir Harry Parkes, Her Majesty's Minister to Japan and China), whilst on a diplomatic mission to the Chinese forces under a flag of truce, had been treacherously taken prisoner with his companions, many of whom died after cruel sufferings. As a punishment for this act of treachery Lord Elgin advanced on Peking and destroyed the celebrated Summer Palace, the British Embassy taking up its quarters in the city in October, 1860. Mr. Lockhart having returned to China for this purpose was able, through his position as medical officer to the Embassy, to establish a hospital in the capital in October, 1861, and during the two and a half years of his stay there over 30,000 patients were treated. Sir Harry Parkes well expressed his estimation of the value of Mr. Lockhart's work in China in one of his letters: "The political good which your proceedings must

Digitized by Google

have will be very great, and your mission will achieve more than the diplomatic in impressing the masses of Peking in our favour. Your hospital I look upon as the most marked incident in our relations with China that has occurred since the signing of the last treaty, and most sincerely do I pray that you may go on and prosper."

Mr. Lockhart finally returned to England in 1864, family circumstances necessitating his relinquishment of active service in the mission field, and he commenced private practice at Blackheath in the following year. From that time until the end of March, 1895, he remained in practice and his devotion to his professional duties during that period was uninterrupted. In the exercise of his profession he was prompt, skilful, and patient of results. Of keen insight, he was always quick at diagnosis and to the very last always prepared for instant response to the call of duty. His loving kindness and tender cheerfulness endeared him to his patients, amongst whom he was always looked for, not only as the trusted adviser, but as the much-loved friend. During these many years of practice he was able, by economy of time and strict punctuality, to maintain his relations with the London Missionary Society, at whose board and stated committee meetings he was a most regular and valued attendant. He had collected a large and valuable library of works on China unique in its variety and comprehensiveness. This he gave quite recently to the London Missionary Society upon certain conditions, which have been carefully carried out, so that it is available for reference at the Mission House and is known as the "Lockhart Library." In his own neighbourhood he held for many years a seat on the board of guardians of the Lewisham Union, and his influence was strenuously exerted to secure the appointment of a resident medical officer and the erection of the infirmary on its present healthy site. He also took part in other local oganisations, where his experience as a medical man was highly valued.

Mr. Lockhart was universally beloved; he was full of life, brightness, and energy up to the very day before his short illness. The devotion and noble self-denial exhibited during his career as a medical missionary were carried through every relation of later life, and a more thoroughly upright and honourable man in all his dealings it would be very hard to find. In the most trying circumstances of his unusually varied life he always exhibited the utmost fortitude, while his kindness of heart endeared him to all who knew him. He married in 1841 Miss Catharine Parkes, the elder sister of Sir Harry Parkes, who survives him, and with whom he had the happiness a few years ago of celebrating his golden wedding, surrounded by a large and loving circle of sons, daughters, and grandchildren.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. F. Vulliet, Professor of Midwifery and Gynæcology in the University of Geneva.

THE CONGRESS OF MEDICINE IN WIESBADEN.

(Continued from p. 1258.)

APRIL 10TH.

The Therapeutic Value of Thyroid Preparations.

PROFESSOR EWALD (Berlin) said that the late Professor Schiff of Florence was the first to show that complete excision of the thyroid gland produces grave and even fatal pathological alterations in the organism; he was also the first to suggest the implantation of small pieces of gland and the hypodermic injection of thyroid fluid in order to counteract these symptoms, and his experimental investigations were turned to practical account by Horsley and Bircher, who administered fresh glands as well as thyroid preparations to patients suffering from various maladies. The efficacy of this was soon recognised, but the active principle of the gland eluded observation for some time, and has only recently been discovered by Professor Baumann of Freiburg, who has succeeded in isolating the so-called thyroiodin, an albuminous compound containing a considerable proportion of iodine. The administration of thyroiodin promotes metabolism, and strong injections of it induce a condition to which the name of thyroiodismus has been given, a group of symptoms comprising anorexia, insomnia, cardiac palpitation, and angina pectoris; the nervous system, also, becomes disturbed and albumin appears in the urine, but the pulse is not affected by thyroiodin when given during only a short period. Glycosuria was observed by Professor von Noorden five times in seventeen cases, but Professor Ewald has never met with this complication. The part played by thyroiodin in the animal economy may be described, according to Professor Ewald, as consisting in the constant introduction of a definite organic iodine compound into the circulating blood, where it destroys certain virulent products the existence of which is inferred from the pathological symptoms developed after the removal of the gland. The thyroid fluid, in fact, acts as an antitoxin against some toxines produced by the normal metabolism of the human body. If the thyroid fluid is deficient or absent these toxines accumulate and symptoms of abnormal metabolism make their appearance, whilst, on the other hand, if it is artificially supplied so copiously that the point of neutralisation is exceeded the result is the state of over-action above described, but this toxic effect is of a transitory character and does not detract from the high therapeutic value of the substance. Thyroid preparations when administered for therapeutic purposes should be given in very small quantities, subsequently increased by degrees. The dose should not exceed ten tablets, containing three milligrammes of iodine, and there will be no unpleasant effects. Thyroid treatment is of the greatest value in myxœdema. Of course, there are frequent relapses when the treatment is discontinued, but soon after it is resumed the patient's condition once more improves. It has also been successfully employed in sporadic or endemic cretinism. In lupus and tuberculosis its efficacy is not so obvious. The thyroid treatment of obesity was first suggested in England and has proved very successful. The daily use of from three to five tablets causes a decrease of body-weight ranging from 4 to 5 kilogrammes (from 9 lb. to 11 lb.) in a week, and in some cases a decrease of even 10 kilogrammes (22 lb.) has been observed. The loss of albumin must be compensated by an albuminous diet. Pure thyroiodin produces the same effects as the tablets; by the daily use of minute doses of this substance a man weighing 96 kilogrammes (= 212 lb.) was found to lose 2 kilogrammes (= 4½ lb.) within a week. In epilepsy, acromegaly, and rachitis its success is very doubtful. In conclusion Professor Ewald said that much has yet to be learned regarding thyroiodin; it is, however, in his opinion, a very powerful therapeutic agent.

Professor BRUNS (Tübingen), following Professor Ewald, spoke on the Thyroid Treatment of Goitre, which he has now carried out in more than 350 cases. It was his experiments on the lower animals which led to the discovery that the administration of thyroid preparations causes the swollen gland to decrease and eventually to regain its normal size. Cystic bronchocele and Graves's disease are not amenable to this treatment. His first cases were treated by fresh thyroid glands and the later ones by thyroid tablets, of which not more than two were ever given to adults, while children had only half a tablet or one tablet, and disagreeable effects were thereby avoided. In his practice there have been only three cases in which the heart became so much affected that the remedy had to be stopped. He has used thyroiodin in twenty-four cases and, as far as he can judge from so limited an experience, he believes this substance, newly discovered by Professor Baumann, to be not less efficacious than the other thyroid preparations. Professor Bruns summed up the results of his observations as follows: 1. The great majority of cases of goitre were benefited by the thyroid treatment. 2. About 25 per cent. remained unaffected; in 8 per cent. the enlargement disappeared altogether; in 33 per cent. portions of the growth continued to persist; and in 33 per cent. the decrease, although obvious, was not very great. 3. The highest proportion of successful cases was found among young persons, the obstinacy of the disease increasing with the age of the patient. 4. The good effects of the treatment became visible in from four to six days; in 60 per cent. the greatest decrease was observed within a fortnight, and in 40 per cent. within three or four weeks. 5. Recovery was most probable and most rapid in the hyperplastic form of goitre. 6. In more than 70 per cent. of the cases the enlargement reappeared after the cessation of the treatment, the relapse beginning sometimes in a month, or sometimes in from three to four months, but resumption of the treatment caused the goitre to diminish once more. Professor Bruns has studied the histological changes presented by

Digitized by Google

the reduced gland, and has found that the colloid substance is augmented, while the follicles are partly dilated and partly atrophied.

Dr. BLACHSTEIN (St. Petersburg) in the course of the discussion called attention to the association of goitre with diabetes.

Dr. MINKOWSKY (Strassburg) said that the thyroid gland had no influence on the production of glycosuria, for the extirpation of the pancreas in dogs on which thyrectomy had been previously performed is followed by glycosuria.

Professor HEUBNER (Berlin) recommended thyroid preparations for rachitis combined with anæmia.

Professor SCHULTZE (Bonn) gave details of a case of tetanus which had been treated by thyroiodin, but without success. In acromegaly, also, it had not in his experience proved to be of any advantage.

Dr. REHN (Frankfort) showed photographs of children who had suffered from cachexia thyreopriva, but who entirely lost their cretinoid aspect after a course of thyroid treatment.

Professor KAST (Breslau) said that thyroid preparations ought not to be taken except under medical supervision. He believed this warning to be very necessary, for he had known cases where persons suffering from obesity had resorted to these remedies against the advice of their medical attendants and serious complications had resulted which might easily discredit the treatment.

The Uric Acid Diathesis.

Professor VON NOORDEN (Frankfort) said that the following rules should be observed in the treatment of the uric acid diathesis. 1. A plentiful use of water. 2. A special dietary unfavourable to the formation of uric acid; that which is usually prescribed does not obviously lessen the formation of uric acid, and a considerable reduction can only be obtained by such a departure from the ordinary way of living as would present many practical difficulties. 3. The administration of substances capable of dissolving uric acid in the urine, especially potassium and lithium salts, piperazine, and lysidine. 4. Abstention from articles such as mineral acids and food containing nucleins, which have the effect of diminishing the solvent power of urine for uric acid. The administration of alkalies, although theoretically correct, requires some precaution. There is no necessity for rendering the urine alkaline, and there is even no objection to its having a slight acid reaction. The best means of retaining the uric acid in solution in the urine is the administration of carbonates or salts of vegetable acids. Among twenty-one patients who were sufferers from the uric acid diathesis and were treated with carbonates and salts of vegetable acids only two had a relapse in the course of a year, although formerly all of them used to have an attack every fortnight. In some cases from 2 to 4 grammes (30 to 60 grains) of carbonate of calcium are sufficient, but in others as much as 20 grammes (three-quarters of an ounce) is requisite.

Professor ROSENFELD (Breslau) said that as the formation of uric acid calculi depends on the amount of free uric acid present in the urine it is very important to ascertain this amount. The determination may be effected by passing the urine regularly through a paper filter; the uric acid retained on the filter is then dissolved in solution of caustic potash, precipitated by hydrochloric acid, and weighed. Urea increases the solubility of uric acid. A patient with a tendency to uric acid deposits should take from 5 to 20 grammes (from 75 grains to three-quarters of an ounce) of urea daily, and his diet should also be carefully regulated. Any increase in the allowance of animal food or in the amount of sugar or fat that is consumed causes a more copious formation of uric acid. Butcher's meat should therefore be replaced by other albuminous substances, such as peptones, casein, or aleuronat, this last being a vegetable albumin, sometimes used as a substitute for bread. The effect of this treatment is to bring about a great reduction in the amount of the uric acid.

APRIL 11TH.

Hepatic Colic of Nervous Origin.

Hepatic neuralgia is not very rare, but is often confounded with gall-stone colic; it has even happened that in a case of neuralgia a surgical operation has been performed owing to wrong diagnosis. According to Professor Fürbringer, in neuralgia the pain is principally localised in the substance of the liver, whilst in gall-stone colic it is of a more diffused character. The duration of an attack varies from ten minutes to four hours. At the end of an attack vomiting is frequent, just as in gall-stone colic, and jaundice has also been observed. The regularity of the attack and the connexion with menstruation are valuable diagnostic symptoms. The disease being a visceral neurosis due to hysteria or neurasthenia the treatment should consist of a strengthening diet, together with a cautious use of appropriate anodynes.

Gouty Affection of the Heart.

Professor SCHOTT (Nauheim) said that the heart diseases associated with gout were first described by Fothergill. Many writers still deny that there is a connexion between gout and heart disease, but Professor Schott has himself observed stenosis of the aorta and myocarditis, as well as sensory and motor neuroses of the heart, which were all undoubtedly due to the gouty diathesis. Cardiac complications often happen in secondary gout, where the stomach, kidneys, and nervous system are affected. The association of gout with anæmia, chlorosis, diabetes, and chronic lead-poisoning sometimes proves disastrous to the heart.

Other Papers.

Considerations of space permit only a passing reference to the other papers read at the final meeting of the Congress, the principal of them being those by Professor OTT (Prague) on the Amount of Albumin in Pathological Fluids, by Professor LEUBUSCHER (Jena) on the Connexion of Heart Diseases with Affections of the Nervous System, by Professor UNVERRICHT (Magdeburg) on the Treatment of Tuberculous Pneumothorax, and by Dr. BLUM (Frankfort) on Enemata of Oil in Gall-stone Colic.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on April 25th the following gentlemen were recommended for the degrees indicated below:—

Degree of M.D. for Practitioners of Fifteen Years' Standing.—Ernest Blacker, M.R.C.S., L.R.C.P., Francis Wheeler Brown, M.R.C.S., L.S.A., John Davies, M.R.C.S., L.S.A., Benjamin Thompson Lowne, F.R.C.S., L.S.A., Robert Mackinlay, L.R.C.P. Edin., L.F.P.S. Glas., Charles Edwin Matthews, M.R.C.S., L.R.C.P., and William Samuel Mavor, M.R.C.S., L.R.C.P.

Degree of M.D.—Burdon Cox, M.B., B.S. Durh., Henry King Dawson, M.B., B.S. Durh., Ebenezer William Diver, M.B. Durh., Frank Hawthorne, M.B., B.S. Durh., Joseph William Leech, M.B., B.S. Durh., Charles Newton Lovely, M.B., B.S. Durh., Henry John Mathews, M.B. Durh., Robert William Morgan, M.B., B.S. Durh., Ogden Watson Ogden, M.B., B.S. Durh., and Samuel Short Whillis, M.B., B.S. Durh.

Degree of M.B.—Honours—Second Class: Vincent Burrow, M.R.C.S., L.R.C.P., St. Mary's Hospital; Edward Harvey Sutcliff, St. Thomas's Hospital; Thomas Streatfeild, M.R.C.S., L.R.C.P., University College Hospital; George Hedley Tomlinson, M.R.C.S., L.R.C.P., and Frank Laughton-Smith, M.R.C.S., L.R.C.P., Mason College, Birmingham; and Thomas Brice Poole, M.R.C.S., L.R.C.P., and Frederick William Rowland, M.R.C.S., L.R.C.P., Guy's Hospital.—Pass List: Percy Luke Armstrong, Leslie Davidson, William Thomas Harkness, Hugh Meyrick Meyrick-Jones, M.R.C.S., L.R.C.P., Herbert Newsome, and William Hunter Richards, College of Medicine, Newcastle-upon-Tyne; John Dee Shapland, B.A. Cantab., University College Hospital; Charles Henry Dickens and Lewis William Richards, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Edward Walter Joscelyne, L.S.A., St. Mary's Hospital; and Charles Holmes Joy and William Henry Whitehouse, Mason College, Birmingham.

Degree of B.S.—Percy Luke Armstrong, Leslie Davidson, William Thomas Harkness, Hugh Meyrick Meyrick-Jones, M.R.C.S., L.R.C.P., Herbert Newsome, and William Hunter Richards, College of Medicine, Newcastle-on-Tyne; Vincent Burrow, M.R.C.S., L.R.C.P., St. Mary's Hospital; Charles Holmes Joy, Frank Laughton-Smith, M.R.C.S., L.R.C.P., George Hedley Tomlinson, and William Henry Whitehouse, Mason College, Birmingham; Thomas Brice Poole, M.R.C.S., L.R.C.P., and Frederick William Rowland, M.R.C.S., L.R.C.P., Guy's Hospital; Lewis William Richards, M.R.C.S., L.R.C.P., St. Thomas's Hospital; and Thomas Streatfeild, M.R.C.S., L.R.C.P., and John Dee Shapland, B.A. Cantab., University College Hospital.

Degree of D. Hyg.—Arthur Edward Thompson, M.B., B.S. Durh.

Diploma in Public Health.—Walter Reyner Brunton, M.B., M.R.C.S., L.R.C.P.

In the third examination for the degree of Bachelor in Medicine under the new regulations the following candidates have satisfied the examiners:—

Second-class Honours.—Albert Gathorne Widdowfield Pearson, College of Medicine, Newcastle-upon-Tyne.

Pass List.—Percy Holgate, Walter Herbert Lister, John Lowry, and William Simpson, College of Medicine, Newcastle-upon-Tyne.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the examiners in

Digitized by Google

Glasgow the following candidates passed the respective examinations, those marked with an asterisk (*) passing "with distinction":—

First Examination: Five Years' Course.—*John Campbell Douglas, Greenock; John B. Conner, Greenock; William A. Ogilvie, Cam, buslang; Charles M'Donnell, Limerick; Edward Michael M'Swiney-Limerick; John Thomas Bradley, Clare; Percy J. Bateman, Cork; Gerald S. Coghlan, Longton; John George Grant, London; and *DanielMichael Donovan, Cork.

First Examination: Four Years' Course.—Frederick George Henderson, Dinapore, India; Louis R. St. Romaine, Calcutta; Alexander E. Crabbe, Aberdeen; John R. Dodds, Darlington; and Charles K. Darnell, Rugby.

Second Examination: Five Years' Course.—*Henry Stewart Anderson, Dunmurry; Alexander Macgregor, Glasgow; William Hutton, Greenock; John Dick, Greenock; Robert W. Jubb, Lowestoft; *Richard Steward, Northfield; James M. Inverarity, Dundee; James Dunlop, Glasgow; William Carey, Glasgow; Thomas D. Bird, Woodford; Harry G. Ogilvie, Jamaica; William J. Aiken, Tyrone; James T. O'Connor, Cork; and Edward H. Harrison, Belfast.

Second Examination: Four Years' Course.—Charles F. Spinkes, Cheshire; Robert M. Quin, Portadown; Tom J. Lumley, Northumberland; Richard E. Roberts, Carnarvonshire; Frederic Lilley, Belfast; James H. Stuart, County Antrim; Mary Ann Handson, Lincolnshire; John Boyd, Kilrea; Michael L. Neylon, Victoria; Farris N. Jaboor, Syria; John G. Gibson, New Cumnock; Montague V. M'Kechnie, Witton Park; Ellis Owen Jones, Carnarvon; James H. Fleming, Avondale; Christopher R. White, Jamaica; and John L. M. Govan, Woolwich.

Third Examination.—Andrew M'Credie, Stranraer, and James M'Glynn, Tyrone.

Final Examination, and admitted Licentiate of the three Coöperating Colleges.—George Henderson, Coatbridge; Ernest Edward Crowther, Luddenden; David Smith Henderson, Coatbridge; James Morrison, Belfast; Patrick James Calnan, Cork; Mark O'Brien, Ballinacollig, County Cork; William Herbert Richardson, Manchester; Annie Christina Sutherland, Bo'ness; Charles Ayton Marrett, London; Daniel Villesid, Belfast; Daniel Morrissy, Passage West, County Cork; Arthur John Pollard, Headingley, Leeds; and Alfred Hamman, Knutsford, Cheshire.

FOREIGN UNIVERSITY INTELLIGENCE. — *Halle:* Dr. Schwartze has been promoted to the position of Honorary Professor of Otology.—*St. Petersburg (Military Medical Academy):* Dr. Boris Verkhovski has been recognised as *privat-docent* in Otology and Rhinology.—*Tübingen:* Dr. W. Küster has been recognised as *privat-docent* in Physiological Chemistry.—*Vienna:* Dr. Leopold Müller has been recognised as *privat-docent* in Ophthalmology.

CHEMISTS' AND DRUGGISTS' EXHIBITION. — The editor of the *British and Colonial Druggist* informs us that in consequence of the success of the practical exhibition of pharmaceutical products and the products of the drug, chemical, and allied trades, which he arranged last year, he is arranging a similar exhibition for next August.

THE annual meeting of the Metropolitan Nursing Association was held on Tuesday last at Grosvenor House under the presidency of the Earl of Strafford. The report gave evidence of much useful work, the number of cases nursed during the year having been 1468. The income for the year was £1890, and exceeded by a little more than £200 the annual expenditure.

HUNTERIAN SOCIETY.—A meeting of this society was held on April 22nd. Mr. Targett gave a Lantern-slide Demonstration of the Changes which occur in the Joints in Charcot's Disease and Syringo-myelia, and pointed out that the lower extremity was chiefly affected in the former disease and the upper extremity in the latter. — Mr. Eve showed specimens of Distortion of the Foot with Trophic Changes in the Joints and Hands from Peripheral Neuritis. — Mr. Cotman brought forward a patient who had an Unusual Condition of the Ankle-joint following a sprain of a year ago; there was an increase in the swelling.—Mr. Charters J. Symonds mentioned the case of a patient who with distinct symptoms of Locomotor Ataxy had Four Perforating Ulcers on his feet, in one of which he had removed the carious head of a metatarsal bone, with successful healing of the ulcer in a fortnight. Curetting of another ulcer had failed, the joint not having been entered. In another patient he removed the head of a carious metatarsal bone with success. He does not consider it always necessary to amputate. The cases may be left alone for long periods.—Dr. Fortescue Fox attributed difference of joints affected in Charcot's disease and in syringo-myelia to the pressure of body weight in the former and to the liability to injury and to degenerate changes of shoulder-joint in the latter, suggesting thus a certain parallelism between syringo-myelia and traumatic or local arthritis.—Dr. Horrocks referred to a case where the removal of a band pressing on the cauda equina in a case of spina bifida occulta had removed symptoms in the feet.—Mr. Targett replied.

THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, VENTNOR.—A dinner in aid of the funds of this institution was held on April 29th in the Whitehall Rooms of the Hôtel Métropole. Sir Richard Webster, Q.C., M.P., was in the chair and was supported by a large and distinguished company. Donations to the amount of £1800 were announced.

THE ROYAL AMATEUR ORCHESTRAL SOCIETY.—A very successful afternoon concert was given in the large room of the Queen's Hall, Langham-place, on May 2nd by the Royal Amateur Orchestral Society for the benefit of the funds of St. Thomas's Hospital. The members of the orchestra played the "Overture from Oberon," the "Overture from Tannhäuser," the "Ungarische Rhapsodien, No. 1," and other pieces with the skill for which they are renowned. Madlle. Irme Sethe (violin), Madame Fanny Moody, Mr. Andrew Black, and Monsieur Sapellnikoff also assisted and were well received. As the room was crowded, every seat having been taken before the day of the performance, we hope that the hospital will receive a considerable sum as the result. Much credit is due to Dr. Toller and those engaged in the preparation of the entertainment.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting was held on April 22nd, Dr. P. H. Pye-Smith, F.R.S., President, being in the chair. Dr. Robert J. Carter, Mr. J. Jackson Clarke, and Dr. C. H. Thompson were elected members of the society. The following cases were exhibited:—By the President: A Symmetrical Pustular Eruption resembling that produced by an Iodide (an unknown medicine having been taken previously to admission into hospital) in a male patient aged fifty-two years, who was suffering from aortic valvular disease.—By Dr. P. S. Abraham: (1) Lichen Planus having unusual Characters on the Legs and Forearms of a Female. (2) Multiple Subcutaneous Tuberculous Nodules in a Girl aged three and a half years; (3) Extensive Dermato-syphilis of Nodular Form of Ten Years Duration in a Woman aged fifty-three years; and (4) Dermato-syphilis of Squamous Form in Two Females aged sixty and forty-three years respectively.—By Mr. L. A. Bidwell: A Boy aged eight years with Persistent Œdema of the Upper Lip of Three Years' Duration commencing with Ulceration inside one Nostril and at the Angles of the Mouth.—By Dr. A. Eddowes: (1) Xerodermia in a Boy specially to illustrate the limitation of the efficacy of thyroid extract as a treatment; and (2) a Girl with Peculiar Œdema of the Right Ear and Cheek, sometimes accompanied by Swollen Eyelids.—By Dr. T. D. Savill: Keratosis Follicularis in a woman aged fifty-eight years.—By Dr. Stowers: (1) Lichen Planus Hypertrophicus in a woman aged sixty-four years; (2) a Papulo-tubercular Dermato-syphilide of Universal Distribution in a woman aged thirty-nine years; and (3) an Unusual Facial Eruption due to the apparent coexistence of Acute Sebacea and Dermato-syphilis.—The President, Dr. Abraham, Mr. Bidwell, Dr. Bowles, Dr. A. Davies, Dr. Eddowes, Mr. Hitchens, Dr. Pegler, Dr. Savill, Dr. Stopford Taylor (Liverpool), and Dr. Stowers took part in the various discussions. It was announced that the annual general meeting and conference would be held on Wednesday, May 20th, full particulars of which would be sent to each member.

THE DIFFUSION OF SMALL-POX.—There were registered in the metropolitan area last week two deaths from small-pox. The deceased persons belonged respectively to Holborn and Newington sanitary districts. The previous deaths from small-pox in London were 2 registered in the first week of March. The cases admitted to hospital last week were only 3 in number, against 5, 4, and 8 in the three preceeding weeks. On Saturday last there remained in hospital only 13 cases of the disease, as compared with 51 and 33 on the corresponding Saturdays of the two previous months. The only other registered death from small-pox in the thirty-three large towns was one at West Ham. There have been several cases recently in Sussex, chiefly in common lodging houses, and in each instance prompt measures of isolation have prevented the spread of infection. Among the cases was one in a tramp from Gloucester, who was staying in a public-house in the hamlet of Hermitage, near Emsworth, and who had the disease in a mild form. The landlord and two other persons have since been attacked, but have been isolated and are now convalescent. A vagrant lad is under treatment in an unoccupied cottage

Digitized by Google

at West Grinstead, in the Horsham rural district. At Gloucester there are signs of waning in the epidemic, the cases in the week ended April 30th having been only 130 as compared with 211, 201, and 168 in the three preceding weeks, while the decline is still maintained. We sincerely trust that the city will shortly be free from its terrible infliction. The fall chronicled was to be expected in view of the activity of the local authorities in carrying out vaccination and revaccination throughout the place. The Gloucester School Board have decided to keep the schools closed until the end of the present month. At a recent special meeting of the Malmesbury Town Council a report was presented by the sanitary officials showing that the case of small-pox found in the place was of mild form in a vaccinated youth, that the patient had been removed to hospital, and that all persons who had come in contact with him had been isolated. No cases have since appeared, and the patient is himself convalescent. A case has occurred at Chew Stoke in the Clutton Union, Neath. In Yorkshire 3 cases have occurred in the North Bierley district. Three men who had been lodging in Bradford fell ill with small-pox, one of them having come from Gloucester. They were removed to hospital, one to Schole Moor Hospital, where he died, and two to Bierley Hall Hospital. The brother of the deceased, who attended his funeral, contracted the disease, from which he also died.

Parliamentary Intelligence.

CURRENT NOTES.

The London Water Question.

In the House of Lords on Thursday, April 30th, there was a long debate on the motion for the second reading of the Government Bill for the establishment of a new water authority for London and the adjoining counties. Lord Tweedmouth moved an amendment to reject the Bill merely on the ground that it takes away the powers of the London County Council, but the House by 98 votes to 27 passed the second reading.

Poor-law Officers' Superannuation Bill.

This Bill is now in so advanced a position and has met with so much favour at the hands of the Government and the House of Commons that it has every prospect of being passed into law before the end of the present session. Its consideration by the Grand Committee on Law occupied a single sitting, and the only amendment of any consequence made was one moved by Mr. T. W. Russell, Parliamentary Secretary to the Local Government Board, providing that resignation as well as dismissal on account of fraud or grave misconduct shall carry with it forfeiture of all claim to a superannuation allowance.

Infant Life Protection Bill.

The Select Committee of the House of Lords on this Bill continues to meet twice a week for the examination of witnesses. Their lordships are quickly bringing together a large body of evidence in favour of extending the present system of registration to persons who take in a single child at a time and continuing the supervision until the child reaches the age of five years. They have examined several officials of the London County Council connected with the administration of the Infant Life Protection Act, several coroners, Mr. Rudolf, Secretary of the Church of England Waifs and Strays Society, and others. A Bill entitled the Safety of Nurse Children Bill has been introduced by Lord Herschell and referred to the committee for their consideration. The promoters of the measure are the National Society for the Prevention of Cruelty to Children.

Midwives Registration Bill.

The promoters of this Bill obtained a place for its second reading among the orders on Wednesday, May 6th, but the Government, in virtue of a recent resolution, put business of their own in front of it and consequently it was not reached at a period of the sitting when it could be discussed. The result is that there is little or no chance of the Bill being discussed this session. The petition of the British Medical Association against the Bill was presented to the House on Tuesday, May 5th.

The Ingredients of British Cigars.

Mr. Gilliat called the attention of the Chancellor of the Exchequer to a statement that in the East of London yellow chestnut leaves were largely used during autumn in the manufacture of British cigars.—The Chancellor of the Exchequer replied that the horrible suggestion had no better basis than a newspaper paragraph. Under the official supervision which exists at present no such operations as those described could be carried on by any licensed manufacturer, and there was no reason to suppose that they were practised by persons not holding a licence.

HOUSE OF COMMONS.

FRIDAY, MAY 1ST.

The Case of Dr. Herz.

In the course of a debate in Committee of Supply on a vote for certain miscellaneous legal expenses, several members called attention to the case of Dr. Herz, complaining that the proceedings against that gentleman had been unduly prolonged and that a great deal of unnecessary expense had been incurred.—Dr. Clark insisted that what had occurred had amounted to persecution.—Sir Matthew White Ridley said, in his reply, that he was quite conscious that the case had cost a great deal of money, although it had been called for partly under our treaty obligations with the French Government and partly by merciful consideration for Dr. Herz himself.—Mr. Lloyd George: Why has the prosecution not been withdrawn?—Sir M. White Ridley: It is for the French Government to withdraw it. We simply fulfil our treaty obligations to France.—Mr. Lloyd George: I do not believe that any treaty compels us to persecute a man who is suffering from heart disease and is on the brink of death by placing a policeman at his door.—Sir M. White Ridley: There is no policeman at the door; he is solely in charge of his own doctor.

MONDAY, MAY 4TH.

Insanitary Barracks.

Mr. Colston asked the Under-Secretary of State for War if he was aware that for the past two years and upwards the sewage from the Le Marchant Barracks, near Devizes, had, owing to a complete breakdown of the sewerage system provided there, been discharged in a crude state into the Kennet and Avon Canal about a mile from the town, and that the canal flows downwards from that point through the town and supplies the water for a public bathing place for the inhabitants; and whether, having regard to the serious danger to health and the annoyance that had arisen, he would forthwith take such measures as were necessary to abate the nuisance.—Mr. Brodrick replied that the measures contemplated in the reply made to his honourable friend a year ago were duly carried out, but from the nature of the subsoil and other circumstances they had not been successful. The case was not quite so bad as represented in the question, for no actual sewage passed to the canal from the barracks, as the latrines were on the dry earth system. The general officer commanding had been given full authority to take any necessary measures and no efforts would be spared to provide a full remedy for the existing admitted evil. The coöperation of the local authorities was needed and had been invited.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (11th).—LONDON POST-GRADUATE COURSE.—Roy. Lond. Ophthalmic Hospital, Moorfields, 1 P.M., Mr. W. Lang: Lacrymal Affections.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. E. Law: Examination of the Nose and Throat.

WEDNESDAY (13th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

HOSPITAL FOR CONSUMPTION, &c. (Brompton).—4 P.M. Dr. Habershon: Mitral Stenosis.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Pemphigus.—Roy. Lond. Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. Q. Silcock: Diseases of Retina, with cases.

THURSDAY (14th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Proteid Substances found in Urine in Disease.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. S. Mackenzie: Clinical Lecture.

VICTORIA HOSPITAL FOR CHILDREN (Tite-street, S.W.).—4 P.M. Mr. D'Arcy Power: Meningitis in its Surgical Aspects.

FRIDAY (15th).—LONDON POST GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Examination of Air, Soil, and Water.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Mr. W. Wingrave: On other Diseases of the Throat and Nose.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

VIEWING THE BODY: A QUERY.

To the Editors of THE LANCET.

SIRS,—Will you kindly answer the following question in your coming number? Is it necessary that the coroner as well as the inquest jury should view the body at an inquiry? I am, Sirs, yours truly,

April 30th, 1896. LEX.

*** There is no doubt that the coroner is as much bound to view the body as the jury. The words of the Coroners Act, 1887 (which is a Consolidation Act), Clause 4, are, "The coroner and jury shall at the first sitting of the inquest view the body."—ED. L.

MONTHLY NURSES AND THE ADMINISTRATION OF ERGOT.

MR. A. BRAXTON HICKS held an inquiry at the Albany Hall, Kingston, touching the death of the newly-born child of John Goodwright. The jury returned a verdict that death was due to the carelessness of Nurse Walker in administering ergot of rye without the advice of the medical man. On arriving the medical man found that his ergot bottle was empty and that the mother had symptoms of an overdose: she was in a state of collapse, the extremities were cold, and the breathing was short and quick. She had to be delivered under chloroform with forceps by Mr. Mackeson. At first the nurse flatly denied having given the ergot; subsequently she admitted having done so. Worse still, she had practised other methods for hastening delivery by kneeling twice on the patient, who was found by Mr. Mackeson to be extensively bruised on the abdomen, over the breast bone, and the last three ribs. Such ignorance and such conduct in a nurse with a certificate from Queen Charlotte's Lying-in Hospital is almost incredible. The element of character, too, assumes great importance in the case. It is well that the mother, under able medical treatment, was saved, or the nurse would have found herself in a very serious predicament.

"A NOVEL METHOD OF INTRODUCING A NEWLY-QUALIFIED MAN."

To the Editors of THE LANCET.

SIRS,—It seems to be particularly unfortunate just now, when the members of the medical profession appear to be waking up to the necessity of standing shoulder to shoulder, that cases such as that related by "Vindicator" in THE LANCET of April 25th should occur. It is no wonder that the public take advantage of us, and by reason of our insane rivalries are enabled to deprive us of our just dues. It shows the necessity of some such association as that which the lawyers have, by which a more strict watch would be kept over the action of its members than the General Medical Council is enabled to do. What appears to me to be most important is—first, a reform of the system of election to the General Medical Council, by which all the members should be elected by the general body of the profession; and secondly, that more power should be given to the General Medical Council in cases in which unprofessional conduct, such as advertising, &c., is indulged in. It would be well if members of the medical profession would join such an association as the Incorporated Medical Practitioners' Association, which is now actively engaged in forming branches all over the country and which can, therefore, bring moral pressure to bear on individuals acting as "Vindicator" describes, and, if necessary, will bring the facts of the case before the corporations who may have granted him diplomas or before the General Medical Council. I am, Sirs, yours truly,

Plymouth, May 5th, 1896. GEO. JACKSON, F.R.C.S. Eng.,
President of the Incorporated Medical Practitioners' Association.

A CORRESPONDENT has sent us a filthy pamphlet entitled "An Essay on the 'Self-Restorer,'" published at 175, Wardour-street, and dated 1895. This pamphlet is written in connexion with a rubbishy apparatus called "Dr. Bell's Self-Restorer Belt," and is a particularly filthy and dangerous example of the quack tract. The person trading at this place under the name of Bell was convicted of using medical titles to which he had no right on Jan. 28th, 1896, at Marlborough-street Police-court (*vide* THE LANCET, Feb. 1st, 1896, p. 310, "A Righteous Judgment"), and we recommend any other of our readers whom this beastliness may reach to forward the pamphlet, envelope, &c., to Scotland-yard, with information as to how it was addressed.

THE CHEMISTRY OF THE BLOOD.

To the Editors of THE LANCET.

SIRS,—In Fownes' "Chemistry" it is stated that "myosin paraglobulin and fibrinogen are readily soluble in dilute acids, but by the act of solution they are at once converted into acid albumin, the precipitate formed by neutralisation being no longer soluble in neutral saline solutions." That from "solutions of acid or alkaline albumin, on careful neutralisation, the whole of the proteid matter is thrown down as a white flocculent, frequently gelatinous precipitate. The action of the acid has converted the albumin soluble in water into a substance insoluble in water. The precipitate is very readily soluble in excess of alkali or dilute acid, and can be reprecipitated by neutralisation. It is insoluble in sodium chloride solution." "Large quantities of acid precipitate it immediately." Again, that "lactic acid coagulates casein." It has been stated that drawn blood decreases in alkalinity while coagulating and that coagulation is prevented by addition of acids or caustic alkali. Can you or any of your readers inform me authoritatively whether, when an organ discharges acid—for example, in rheumatism or gout lactic or uric acid—into the blood during life, a similar or analogous precipitation to that above stated does or does not take place, and whether the disease of blood-clotting ever so arises? Has the effect of alkalies in thrombosis, embolism, or paralysis from clot been noted, and could you refer me to any treatises on the point? I am, Sirs, yours truly,

May 5th, 1896. E. L. E.

RHEUMATOID ARTHRITIS.

To the Editors of THE LANCET.

SIRS,—The interesting paper by Dr. Bannatyne, Dr. Wohlmann, and Dr. Blaxall in THE LANCET of April 25th recalls to my mind a point in regard to patients suffering from rheumatoid arthritis which I have not seen noticed—namely, their dislike to any warm clothing or covering. This is the more remarkable because it is directly opposed to what we find in sufferers from all other kinds of rheumatism, who know well the value of swathing themselves in flannel. Two well-marked cases of this occur to me. One is that of a woman aged sixty years who has been bedridden with the complaint for over a dozen years, who lives in a cottage in a bleak village in the Midlands, and whose habitual covering is a sheet and counterpane. The other is that of a woman, who died after many years' suffering in early middle life. She absolutely used to refuse to wear any flannel underclothing, and in the depths of winter would retire to rest without any fire in her room, although, owing to her crippled state, it would sometimes take her over a couple of hours to undress and get into bed. On trying to elicit from patients the reason they dislike warm clothing it appears, as far as I can gather, to be not fear of an increase of pain or of sweating, but a dread that it will bring on faintness or syncope, perhaps because the additional warmth would still further stimulate the already too quickly acting heart and tax and distress it. I am, Sirs, yours faithfully,

May 2nd, 1896. WALTER G. EARLE, M.R.C.S.Eng., L.R.C.P.Lond.

WANTED, A SUGGESTION FOR TREATMENT.

To the Editors of THE LANCET.

SIRS,—I have a patient thirty-four years old, strong and healthy, who is a van driver; he has a strong, thick, black beard which he has been in the habit of shaving, which habit he has had to discontinue because of the outbreak of a crop of warts. The warts appeared suddenly about eight weeks since; they extend from the angle of the jaw on the right side to the corresponding one on the left side; they are small in size except a few which have outgrown the others, and they are to be counted by the hundred. Can any reader offer a suggestion for their removal? I am, Sirs, yours truly,

May 4th, 1896. PUZZLED.

H. H., M.D.—The newspaper cutting enclosed by our correspondent contains regrettable matter. But in spite of the fact that the personal information purports to have been given in an interview, we consider it probable that the medical man is suffering from a friend's indiscretion, and has not been himself a party to the dissemination of his praises. Such a practice as the medical man in question has enjoyed was certain to bring him into contact very closely with many persons quite ignorant of medical etiquette, any one of whom might have assisted in the publication of the offending paragraphs from the best of grateful motives.

TOO MANY PARTICULARS.

To the Editors of THE LANCET.

SIRS,—I would like your opinion in the forthcoming issue of THE LANCET on the merits of the following case. A patient of mine died from catarrhal croup who presented all the symptoms of asphyxia; that is, in my opinion, the child died from deficient oxygenation of the blood due to the obstruction in the larynx. Accordingly I filled up my certificate as follows: "Primarily, catarrhal croup; secondarily, carbonic acid poisoning." This certificate I gave to the parents, and on presenting it to the registrar it was refused and they were told to go to the police. The police directed the people back to me and I gave them a detailed letter to the registrar explaining the cause of death. This he also rejected, and the police then had to communicate with the coroner, who on reading the certificate and letter issued an order for burial. My death certificate was thrown about the police office, whence I afterwards took it and gave it to my solicitor. In consequence of the action of the registrar the rumour has gone forth that, first, I poisoned the child, and, secondly, that my certificates will not be accepted. This has done me a great amount of damage, financially and professionally. The people now, when cases I am attending become serious, call in another doctor in order that the certificate may be all right. I have only been in practice here a little over a year, and my name and reputation are all I have to depend upon.

Section 20 of the Births and Deaths Registration Act, 1874 (37 & 38 Vict., c. 88) says:—

> "In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death, a certificate stating to the best of his knowledge and belief the cause of death, and such person shall upon giving information concerning the death, or giving notice of the death, deliver that certificate to the registrar, and the cause of death as stated in that certificate shall be entered in the register, together with the name of the certifying medical practitioner."

The registrar here is not a medical man. I am, myself, a registered practitioner since 1888. I have given the matter into the hands of my solicitor, but I wish myself to be fortified by your great experience.

I am, Sirs, yours truly,

April 27th, 1896. EDWARDUS.

*** Our correspondent went too much into particulars. He gave a sufficient cause of death in catarrhal croup. In using the words "carbonic acid poisoning"—accurate enough in a scientific sense—he gave information which was too much for the recipients, who have to use such judgment as they have in referring certificates to the police or the coroner. They might have acted with more respect to the certifier, but the only revenge we should advise is very scant doses of pathological information in future in his certificates to such an inappreciative registrar. Pearls are only beautiful to the capable eyes.—ED. L.

Sudens.—We have reviewed the periodical in question and have not found the numbers noticed wanting in taste. Its career is already determined.

THE RADNOR WATER CO., OF MONTREAL, CANADA.

THIS company send us further samples from their spring. Having recently examined this interesting water, which is a purely natural one and delicate to the taste, there is no need for further examination, especially as it was the subject of an analysis published in THE LANCET of Jan. 18th last, p. 173.

Ambulance.—It seems to us that B. and C. should meet and determine to be amicable. C. has a right to accept the invitation, but B.'s sense of grievance is not unnatural.

THE PUBLIC ADVERTISING OF MEDICAL BOOKS.

To the Editors of THE LANCET.

SIRS,—A placard, of which enclosed is a copy, has been for some days posted on the wall by the side of the shop window of Messrs. Cornish, booksellers, New-street, Birmingham. The placard is some two feet long and six inches wide, and the letters large and conspicuous. The Royal College of Physicians of London ought to be proud of its Fellows.

I am, Sirs, yours truly,

Birmingham, April 28th, 1896. HONOR.

[COPY.]

NAUHEIM (SCHOTT) TREATMENT OF HEART DISEASE.
BY
R. SAUNDBY, M.D., F.R.C.P.

*** We are confident that this advertisement cannot have come to the notice of Dr. Saundby himself and that he will now take immediate steps to stop such an objectionable parade of his name and his writings. The enterprising tradesman will, we fear, never be brought to see that "Publicitas publicitatum, omnia publicitas" is *not* the motto of the medical profession.—ED. L.

Mr. N. W. Holmes is thanked for his communication.

MEDICAL SOCIETY (COURT FORESTERS' ISLE, NO. 1822).

WE have received from a correspondent a balance-sheet of this medical aid society. It does not contain details of the number of patients attended, number of visits made, &c., so that there is no way of estimating whether the rate of payment is one that should be accepted by the medical officers; but in any case these medical officers, viz., Dr. W. Hoffmeister, Mr. J. B. Hoffmeister, and Mr. B. Watson Paul—should insist upon having the lyric effusion with which it terminates removed. It is discreditable to these gentlemen that their names should be brought before the public in this manner. We append the sinning verses:—

> "Where are you going to, my pretty maid?
> To the Foresters' Hall, kind Sir, she said.
> Why are you going, my pretty maid?
> Oh, I am going to join the Medical Aid,
> It's a first-rate society, kind Sir, she said.
> Who are the doctors, my pretty maid?
> Messrs. Hoffmeister and Paul, kind Sir, she said.
> Then all should join it, my pretty maid!
> Oh, yes, oh, yes, kind Sir, she said."

An Old Subscriber.—The practice is time-honoured. But it is in these days more honoured in the breach than in the observance. In many places the poorer patients look for the sign.

THYROID FEEDING.

To the Editors of THE LANCET.

SIRS,—I should be grateful if any of your readers could give me some information on thyroid feeding by the fresh gland, with especial reference to the following points—(1) quantity for, say, a week; (2) mode of preparation; and (3) dangers of excess, if any, and symptoms of same.

I am, Sirs, yours faithfully,

April 26th, 1896. P. W.

Sufferer has omitted to enclose his card.

ERRATUM.—We regret that the words "senior surgeon, Ancoats Hospital," should have been added to Dr. Martin's communication last week. The correct reading is—late senior house-surgeon, Ancoats Hospital.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*South Wales Daily News, Birmingham Gazette, Huddersfield Chronicle, Eastern Daily Press, Western Morning News, West London Observer, Wolverhampton Chronicle, Craven Herald, Brighton Gazette, Elgin Courant, Kentish Express, Southampton Times, Liverpool Daily Post, Grimsby News, Goole Times, Hampshire Independent, Sussex Daily News, Leyton Independent, Bury Guardian, Stroud News, Arbroath Guide, Bristol Mercury, Highland Times, Salisbury Journal, Birmingham Mail, Yorkshire Post, Manchester Courier, Liverpool Courier, Leeds Mercury, Sheffield Independent, Contractors' Chronicle, Kendal Express, Builder, Ayrshire Weekly News, Times of India, Galloway Gazette, Pioneer Mail, Architect, Sanitary Record, Le Temps, New York Herald, North China Daily Mail, Madras Times, New Zealand Herald, Bombay Gazette, Montreal Herald, Reading Mercury, Mining Journal, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Hemel Hempstead Gazette, City Press, Hertfordshire Mercury, West Middlesex Standard, Local Government Journal, Surrey Advertiser, Walsall Observer, Walsall Free Press, Penrith Observer, Guernsey Star, Kelso Mail, Cumberland Advertiser, Citizen, Tablet, Electricity, English Mechanic, Building News, Airdrie Advertiser, Whitehaven Free Press, West Cumberland Times, Cape Times, Loughborough Monitor, North Devon Herald, Langport Herald, Thanet Guardian, Lincolnshire Echo, Public Health, &c., &c.*

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Amières, Paris.

The Arris and Gale Lectures

ON THE

PHYSIOLOGICAL FACTORS INVOLVED IN THE CAUSATION OF DROPSY.

Delivered before the Royal College of Surgeons of England on Feb. 17th, 19th, and 21st, 1896,

BY ERNEST H. STARLING,
M.D. LOND., M.R.C.P.,
JOINT LECTURER ON PHYSIOLOGY AT GUY'S HOSPITAL.

LECTURE II.[1]

THE ABSORPTION OF FLUIDS FROM THE CONNECTIVE TISSUE SPACES.

MR. PRESIDENT AND GENTLEMEN,—We have now to consider the second physiological factor which is involved in the production of dropsy. Two ways of absorption have been generally described—viz., absorption by the lymphatics and absorption by the bloodvessels; and we find that at different periods in the history of the subject each of these has in turn been looked upon as the most important, or even exclusive, channel. There can be no doubt that absorption may take place by both these ways. Since the mechanism of absorption by the lymphatics is the more evident and familiar we may consider this way first.

All parts and organs of the body possess a well-developed system of lymphatics. These channels are in direct communication with the tissue-spaces and can be easily injected from these spaces. They are lined by a layer of endothelial cells, which are continuous except at the very point of junction of the lymphatics with the tissue-spaces. The larger trunks possess also an outer wall of connective tissue in which in some situations we find unstriated muscular fibres. All the lymphatic trunks, with the exception of those draining the upper extremity and right side of the head and neck with the adjacent parts of the thorax, converge to join the thoracic duct, which pours its contents into the blood in the angle between the left jugular and subclavian veins. All the larger lymphatics possess numerous valves so arranged that the lymph can only flow in them towards the thoracic duct. It is evident from these anatomical arrangements that any excess of fluid in the connective tissue spaces will make its way into the lymphatics and so finally attain the blood by way of the thoracic duct. There is one point, however, which I think is not sufficiently appreciated, and that is the importance of muscular movements both for emptying the spaces into the lymphatics and for propelling the lymph onwards through the lymphatics. If we have a manometer in the peripheral end of one of the lymphatics of the leg and inject fluid under pressure into the connective tissue spaces of the foot we find that the manometer in the lymphatic rises extremely slowly, so that the pressure in the spaces may be many times the pressure that obtains in the lymphatic. We have now only to flex the foot on the leg once or twice to immediately send up the pressure in the lymphatic to a height equal to or above that in the connective tissue spaces. Our knowledge of the importance of muscular movement for the normal lymph-flow we owe to the labours of Ludwig and his pupils. In all tendons and aponeuroses we find a double system of lymphatics—a deep system, consisting of vessels running parallel to the tendon-bundles and communicating by cross branches, and a superficial network with polygonal meshes in the peritendinous connective tissue. Both networks are in direct communication and either of them possess any valves. The superficial network trains into larger lymphatic trunks provided with valves. Each time that the underlying muscle contracts the deeper system is pressed upon and its contents emptied into the superficial system and so into the valved lymphatic trunks. When the muscle relaxes the fluid cannot get back past these valves, so that the two systems of lymphatics are emptied and ready to receive more fluid from the connective tissue spaces. A similar double system was described long ago by Ludwig and Schweigger-Seidel in the central tendon of the diaphragm, and these writers showed how beautiful injections might be made from the peritoneal cavity by injecting Berlin blue into this cavity and then carrying out artificial respiratory movements. As I have mentioned in my last lecture, it is impossible without such aid as muscular movements or passive flexion and extension of the limb to get any lymph-flow at all from a cannula placed in the lymphatics of the leg or arm. It will be evident to you therefore what an imperfect conception of the normal lymph-flow we obtain from a study of the flow in an animal anæsthetised and secured on its back on the operating table, when during normal existence every breath we draw and every movement or twitch of the muscles helps to pump lymph from the extremities into the thoracic duct and so into the blood.

Much more difficulty exists with regard to the absorption of fluid from the connective tissue spaces by the bloodvessels, and this question has been the subject of many investigations. Many years ago Majendie devised a number of ingenious experiments in order to show that poisons introduced into the serous cavities and connective tissue spaces of the limbs were absorbed not by the lymphatics but by the bloodvessels. These researches have been continued and extended of late years by Ascher in the case of the connective tissues of the lower limbs, by Tubby and myself in the case of the pleural and peritoneal cavities. We found, for example, that after injecting methylene blue or indigo carmine into the pleura the dye-stuff appeared in the urine within five minutes, whereas the lymph presented no trace of blue for another twenty minutes or even two hours. It is evident then that in this case the dye must have been taken up by the bloodvessels and not by the lymphatics, and that this vascular absorption takes place with extreme rapidity. In a later series of experiments Leathes has shown that after introduction of various salt solutions into the serous cavities an interchange of constituents takes place directly between the blood and the injected fluid, so that the latter in a very short time becomes isotonic with the blood plasma. Now in this mode of absorption by the bloodvessels the so-called absorption really consists in an interchange between blood and extra-vascular fluids—an interchange apparently dependent entirely upon processes of diffusion between these two fluids. So long as any difference in composition exists between intra- and extra-vascular fluids so long will diffusion-currents be set up tending to equalise this difference. This power of interchange between blood and tissue juices is probably of great importance in the normal metabolism of the tissues. Supposing, for example, that a tissue cell is storing up in itself a large amount of calcium or secreting it away from the tissue fluids into the lumen of a gland duct, it is evident that the percentage amount or partial tension of the calcium salts in the fluid surrounding the cell will be diminished. Diffusion currents will therefore be set up, and there will be a flow of calcium from the blood to the lymph until the normal calcium tension is restored. We must conclude, therefore, that for the ordinary metabolic activities of the tissues no lymph-flow at all is necessary, the cell being able to obtain all its diffusible food stuffs from the blood by means of diffusion even through a stationary layer of lymph.

These experiments, however, have no direct bearing upon the absorption of dropsical fluids by the bloodvessels. In the case of dropsical fluids the exudation resembles in all points blood plasma, the only difference between the two consisting in the fact that the dropsical fluid is rather poorer in proteids than the plasma. Here, as we have fluids almost identical on each side of the endothelial wall of the vessels, no conditions are present which would favour the setting up of diffusion currents. As a matter of fact, we may say that diffusion currents bring about an interchange of constituents between the two fluids, but can under no circumstances effect a total absorption of fluid. We have therefore to inquire whether, under any circumstances, an absorption of dropsical fluids or of isotonic salt solutions can be carried out by the bloodvessels. We may arrange the experiments upon this point under three headings.

1. In the first set observations were made on the absorption of isotonic salt solutions and blood serum from the pleural and peritoneal cavities. Orlow, working under Heidenhain's direction, found that such fluids were absorbed rapidly from the peritoneal cavities of living animals, while

[1] Lecture I. was published in THE LANCET of May 9th, 1896.

Digitized by Google

the lymph-flow from a cannula placed in the thoracic duct showed no (or only slight) increase in no way comparable to the amount of fluid absorbed. He concluded, therefore, that the absorption was affected by the bloodvessels, and was dependent on the vital activity of the cells lining the serous cavities or of the endothelial cells of the capillaries. Leathes and Hamburger confirmed these results, but showed that they could not depend on any vital activity of the endothelial cells, since absorption took place with equal rapidity even when poisonous solutions of sodium fluoride were made use of. The great objection to these experiments is that they do not prove conclusively absorption by the bloodvessels. It is still possible that the fluids had been taken up by the sub-serous lymphatic network and had not reached the thoracic duct during the experiment. This is an objection raised by Cohnstein, who concludes from very similar experiments that these fluids are carried away solely by the lymphatics. It might be thought that this question could be easily decided by observing whether fluids were still taken up from the serous cavities after ligature of both thoracic ducts. I have made a number of experiments of this description, but have failed to get decisive results. It is true that after ligature of both thoracic ducts as well as of the right innominate vein isotonic salt solutions were taken up fairly quickly from the serous cavities. In none of these cases, however, could I be certain that the lymph was absolutely shut off from the blood. As a rule I injected on three succeeding days several hundred c.c. salt solution into the peritoneal cavity, the last injection containing carmine granules in suspension. On killing the dog two days after the last injection the peritoneal cavity was generally found to be empty, and carmine granules could be traced along the glands of the anterior mediastinum, showing that, in spite of the ligature of both thoracic ducts, there had been a passage of lymph upwards and through the chest. We must, therefore, look to other methods to decide this question.

2. There are a whole series of experiments made by other observers which to my mind prove conclusively the power of the bloodvessels to take up fluid from the tissue spaces. If an animal be bled several times it will be found that the blood obtained in the later bleedings is more watery than that obtained at the beginning of the experiment. Now this diminution of total solids in the blood seems to be due chiefly to a dilution of the serum; the serum contains less solids than before and is increased in volume relatively to the blood corpuscles. I may here quote some observations which show this point.

Dog, 11·4 kilos. Solids of serum = 7·72 per cent. Dog then bled to 220 c.cm. Thirty minutes later solids of serum = 7·14 per cent.

In another experiment the solids of the serum were at first 6·98 per cent.; after bleeding to 200 c.cm. = 6·57 per cent.; after further bleeding to 100 c.cm. = 6·37 per cent.

In a smaller dog (6·5 kilos.) withdrawal of 150 c.cm. blood reduced the solids of the serum from 7·77 per cent. to 6·47 per cent.

It must be noticed that this attempt to regulate the amount of the circulating blood by bringing it up to its normal volume is carried out with great rapidity, so that even while we are bleeding an animal we find that the later portions of blood are more dilute than the earlier portions. That the fluid which is added to the blood in these cases is derived from the tissue spaces is shown by Barlow's experiments. Now this dilution of the blood takes place even when the thoracic duct is tied or when the lymph is conducted away by placing a cannula in the duct, so that it cannot be due, as was formerly thought, to an increased lymph-flow into the blood.

3. In order to be absolutely certain of the power of the bloodvessels to take up isotonic solutions and dropsical fluids from the tissue spaces I have carried out a series of experiments in which I led defibriated blood through the bloodvessels of amputated limbs. In each case I had a double set of transfusion apparatus and sent one-half of the blood many times through a limb which had been rendered dropsical by the injection of isotonic salt solution, while at the same time fluid was flowing at the same pressure through the other limb, which was not dropsical, and thus served as a control. In each case the blood was analysed and its hæmoglobin estimated before the experiment and from both limbs after the experiment. It was invariably found that, whereas the blood which had passed from twelve to twenty-five times through the sound limb had become rather more concentrated, the blood which had passed through the œdematous limb had taken up fluid from this limb. I may here quote one of these experiments as an example:—

—	Total solids.	Percentage of HbO_2.
1. Blood before experiment	21·2%	100
2. After twenty passages through normal leg ...	21·4%	103
3. After twenty passages through œdematous leg	20·5%	96·5

We must conclude, then, that isotonic salt solutions and dropsical fluids may be taken up by the blood circulating through the capillaries and that this process may occur fairly rapidly. In the last lecture we saw how any excess of intra-capillary pressure, such as accompanies plethora, causes an increased transudation from the capillaries, so that the volume of circulating fluid is diminished. Now we see that, on any diminution of capillary pressure taking place, as after bleeding, the fluid in the tissue spaces goes back into the vessels to make up for the volume of circulating fluid lost. This wonderful balance between capillary pressure and lymph production or absorption is, I think, well illustrated by Lazarus Barlow's observations. While not agreeing with my views on lymph-production, this observer has shown that the slight plethora produced by wrapping up the limb in Esmarch's bandage causes an appreciable increase in the transudation in other parts of the body, so that the specific gravity of the tissues of the upper limb, for instance, falls, while the specific gravity of the blood rises. The reverse is the case when circulation is restored to a limb which has been kept anæmic for an hour or two. Here there is considerable hyperæmia of the affected limb produced, and corresponding anæmia of other parts of the body. We find then that absorption as well as transudation through the capillary wall is determined by the intra-capillary pressure. When the pressure rises transudation is increased, when the pressure falls absorption is increased. We have seen that the dependence of transudation on capillary pressure is susceptible of a fairly simple mechanical explanation (filtration hypothesis). We have now to discuss the mechanism of the absorption process.

Is absorption effected by the active intervention of the endothelial cells or are there physical factors at work which will serve to explain it? An explanation of absorption which will strike anyone who investigates this problem is the possibility that absorption may take place in the same manner as lymph production—i.e., by a process analogous to filtration. From the work of Ludwig and Noll we know that the pressure in the lymphatics is extremely low; but the experiments I mentioned earlier in this lecture show that there may be a considerable pressure in the tissue-spaces without communicating itself to the fluid-filling lymphatics. Landerer, who has written a whole book on the subject of tissue tension, places the pressure in these spaces at a high level, from one half to three-quarters of the capillary pressure. It is evident that if this were the case and the capillary pressure suddenly sank 50 per cent. the pressure in the extra-vascular spaces would be higher than that in the capillaries and a backward filtration of lymph might occur. A series of mechanical experiments by Klemensiewicz would seem at first sight, however, to show that such a backward filtration is impossible. Klemensiewicz points out that if fluid be passing at a given pressure through a permeable tube contained within a rigid tube transudation will occur until the pressure of the transuded fluid is equal to that of the fluid flowing through. At a certain point in the experiment the pressure of the transuded fluid will exceed the pressure at the outflow end of the tube. The tube will collapse and the flow through it be stopped. He imagines that the same sequence of events occurs in the living body in the presence of a considerable transudation. Arteries, capillaries, and veins are bathed in the transuded fluid. The fluid transuded from the capillaries will, if a free outflow for it be absent, after a time attain a pressure near that ruling in the capillaries and higher than that of the venous pressure. The veins will therefore collapse, venous obstruction will be produced, and the capillary pressure and transudation will be higher than ever, so that we have a vicious circle of events tending continually to increase the œdema of that part. Now, Klemensiewicz's objections are true only under one condition—i.e., that the venous tubes should run

Digitized by Google

freely through the lymphatic spaces of the tissues. If, however, we consider a system in which the inner tube is connected at various points in its circumference to the outer tube by strands of inextensible fibres, it is apparent that a rise of pressure in the space surrounding the inner tube will only serve to extend this tube still further. No collapse will take place, but a back filtration will be possible. Now, if we cut sections of injected connective tissues we find that the capillaries are bound to surrounding parts by radiating fibres which might possibly prevent their collapse under high extravascular pressure. In the larger veins, on the other hand, the arrangement of the fibres of the adventitia is circular and not radial, so that a high extra-vascular pressure would apparently cause collapse of the veins. From these anatomical facts one would conclude that a backward filtration is possible provided that the extravascular pressure be raised only in the region of the capillaries. If, however, the pressure be freely propagated through the tissues so as to affect the larger veins draining them we shall have collapse of the veins and increased edema. Here, as in so many other cases, we cannot get a decisive answer to our physiological questions by purely anatomical investigation, but must have recourse to physiological experiment.

The question that we have immediately to decide is whether an increased tissue tension augments or leaves unaltered the flow of blood through the tissues or whether it causes venous collapse and so diminishes the flow. In the former case a back filtration would be possible and in the latter case impossible. I have investigated this point in various regions of the body, the connective tissues of the leg, the tongue as a type of muscular tissue, and the submaxillary gland as a type of glandular tissue. In all these cases I have found that a rise of tissue tension above the pressure in the veins causes collapse of these veins, a rise of capillary pressure, and a diminished flow of blood through the part. In these regions of the body, therefore, absorption of lymph by a backward filtration is impossible.

Hamburger, finding that serum and isotonic fluids are absorbed from the peritoneal cavities that had been dead some hours, concludes that the life of the endothelial cells can have nothing to do with the process and ascribes the absorption to processes of capillary and molecular imbibition, so that the absorption of fluids would be analogous to the taking up of fluids and gases by animal charcoal. Though these factors probably coöperate to a certain extent in the distribution of the fluid through the tissues surrounding the serous cavities, it is evident that they would be much more pronounced in dying and disintegrating tissues, and could with difficulty explain the taking up of fluids by the bloodvessels. They would certainly not explain the wonderful balance which exists between the intracapillary pressure and the amount of fluid transuded from or absorbed by the bloodvessels. What, then, is the explanation of this absorption? The explanation is, I believe, to be found in a property on which much stress was laid by the older physiologists and which they termed the high endosmotic equivalent of albumin. It must be remembered that the older physiologists used animal membranes in their experiments on osmotic interchanges. These membranes permit the passage of water and salts but hinder the passage of coagulable proteid. The application of semi-permeable membranes to the measurement of osmotic pressures showed that the osmotic pressures of salts and other crystalloids are enormously higher than those of colloids such as albumin, and it has therefore been supposed that the osmotic pressure of the proteids in the serum being so insignificant must be of no account in physiological processes. The reverse is, however, the case. Whereas the enormous pressures of the salts and crystalloids in the various fluids of the body are of very little importance for most physiological functions, the comparatively insignificant osmotic pressure of the albumins is of great importance and for this reason. It has been shown that bodies in solution behave in most respects like gases. Now there can be no difference in pressure between two gases in a vessel which have no partition between them or only divided by a screen freely permeable to both gases. In the same way if we have two solutions of crystallised substances separated by a membrane which offers free passage to the water and the salts on either side there can be no enduring difference of the osmotic pressure on the two sides, especially if a free agitation of the fluids on both sides is kept up. The pressures on the two sides will be speedily equalised, and then any flow of fluid from one side to the other will cease. Now the capillaries in the living body represent such a membrane. Leathes has shown that within 5 minutes after the injection of sugar or salt into the bloodvessels the osmotic pressures of the blood and lymph have become equal. Supposing, however, that we have on one side of this membrane a substance to which the membrane is impermeable, this substance will exert an osmotic pressure and will attract water from the other side of the membrane with a force proportional to its osmotic pressure. This attraction of fluid must go on until all the fluid has passed through the membrane to the side where the indiffusible substance is.

Now the capillaries of the body are almost impermeable to proteids. In consequence of this impermeability the fluid which is transuded from the capillaries under pressure contains very little proteid. From what I have just said it follows that the proteid left in solution within the capillaries must exert a certain osmotic attraction on the salt solution outside the capillaries. It is easy to measure the value of this attractive force. If we place blood-serum in a small thistle funnel over the open end of which is stretched a layer of peritoneal membrane soaked in gelatin, and immerse the inverted funnel into salt solution which is isotonic or even hypertonic as compared with the serum, within the next two days fluid will pass into the funnel and will rise in its stem to a considerable height. I have found that the osmotic pressure of the non-diffusible portions of blood-serum measured in this way amounts to 40 mm. Hg. Now you will see at once the importance of this fact. Although the osmotic pressure of albumin is so insignificant, it possesses an order of magnitude comparable to that of the capillary pressures, and whereas capillary pressure determines transudation the osmotic pressure of the proteids of the serum determines absorption. Moreover, the osmotic attraction of the serum for the extravascular fluid will be proportional to the force expended in the production of this extravascular fluid, so that at any given time there must be a balance between the hydrostatic pressure of the blood in the capillaries and the osmotic attraction of the blood for the surrounding fluids. With increased capillary pressure we shall have increased transudation until we get equilibrium established at a somewhat higher point, when there is a more dilute fluid in the tissue spaces, and therefore a higher absorbing force to balance the increased capillary pressure. With diminished capillary pressure there will be an osmotic absorption of salt solution from the extravascular fluid until this becomes richer in proteids, and the difference between its osmotic pressure and that of the intravascular plasma is equal to the diminished capillary pressure.

Here, then, we have the balance of forces necessary to explain the accurate regulation of the quantity of circulating blood, according to the conditions under which the animal may be placed, and it seems unnecessary to invoke the aid of vital activity to explain the process. Certain corollaries of this mode of explanation agree well with observed facts of experiment. Thus, the more impermeable the capillary the smaller will be the amount of proteid exuded with the lymph. A higher capillary pressure will therefore be needed in its production and there will be an equally high force tending to its reabsorption. A rise of capillary pressure will only increase the amount of lymph in the extravascular spaces to a certain extent, but will at the same time cause this lymph to be more dilute, so that there will be a corresponding rise in the force tending towards absorption. In consequence of this sequence of events considerable alterations of capillary pressure may be produced in impermeable capillaries, such as those in the limbs, without causing any appreciable increase in the lymph-overflow from the limbs. On the other hand, where the capillaries are very permeable very little pressure will be required to cause a transudation, since no work is done in the concentration of a proteid solution, and we find, as a matter of fact, that capillaries where the pressure is lowest—i.e., in the liver—are also those which are the most permeable. Here, moreover, the absorbing force will be insignificant, since there is very little difference in the percentage of albumin between liver blood and liver lymph.

This osmotic difference between blood plasma and tissue fluid will not serve to explain the absorption of proteids by the bloodvessels and would certainly not explain the absorption of serum from the serous cavities. It is difficult, however, if not impossible, to prove that serum or proteid is absorbed by the bloodvessels. In some of my transfusion experiments I

Digitized by Google

have rendered a limb œdematous by means of serum, and in these cases have obtained no evidence at all of absorption by the bloodvessels. There is no doubt that serum may be absorbed from the pleural and peritoneal cavities, but the absorption of these fluids is very much slower than the absorption of salt solutions, and is in fact so slow that the whole of it can in most cases be effected by the lymphatic channels. A slow absorption of serum from tissue spaces by means of the bloodvessels is also physically possible. As the cells of the tissues feed on the proteids of the fluid the serum will tend to become weaker and weaker, so that the watery and saline constituents corresponding to the proteid used up can then be absorbed by the bloodvessels in the way I have indicated.

The physical process which I have described above as causing the absorption of lymph by the bloodvessels must be in action at all times in the body and must, therefore, be a predominant factor in the process of absorption. I have not been able to absolutely exclude the absorption of proteids by the bloodvessels, but, in the absence of direct experimental evidence that such an absorption does occur, the physical factors I have described in this lecture suffice to explain the phenomena of absorption observed both under normal and under pathological conditions.

An Address
ON
THE CAUSE OF MALARIA.

Delivered at the Grant Medical College, Bombay, on April 4th, 1896,

BY SURGEON-LIEUTENANT-COLONEL E. LAWRIE, M.B. EDIN.,
RESIDENCY SURGEON, HYDERABAD.

GENTLEMEN,—The subject of malarious fever is one which belongs more properly to the physician than to the surgeon, but everyone in India, whether he practises medicine or surgery, is constantly called upon to deal with malaria and its effects. Moreover, it is notorious that for more than a year the whole of the medical profession in India has been smarting under a series of insults and slurs, which I shall take this opportunity of showing are wholly unmerited, that have been cast upon us by the *British Medical Journal*. This journal has been conducting a campaign on its own account against the sanitary services in India in which the microscopic "parasite" of malaria has so far been its biggest gun. Statements have appeared from time to time that the "parasite of malaria is the greatest discovery in pathology." "If there is one thing certain in pathology it is that a living parasite is present and can be invariably found in malarial blood." "It is by far the most important of the animal parasites affecting man." "Eyes sharp and trained as those of Virchow and Frerichs completely failed to recognise it lying patent under their very noses." "The investigation of these bodies is the principal business and main duty of the Indian physician." "It has been entirely, or almost entirely, neglected by the profession in India." Men who write of Laveran's bodies as "pets," "beasts," "brutes," or (save the mark!) "bugs" have been extolled in the *British Medical Journal* as scientists in terms of the highest praise, while senior men of the calibre of J. M. Cuningham, Bryden, Rice, Marston, D. D. Cunningham, Crombie, Sanders, and a host of others, whose names alone call up feelings of respect and admiration throughout the length and breadth of this land, have been as freely reprobated. In short, a reign of terror has been established which must soon make it impossible for the profession to hear more than one side of any of the great medical questions of the day. The journal has gloried in "bombshells" and "hard-hitting" apparently unmindful of the fact that two can employ these offensive weapons. It is just possible, though highly improbable, that the designation of the present honoured head of our service as "Surgeon-Major Cleghorne" is a printer's error, but it is quite impossible that anyone in Calcutta or in India could have written of the "Offices of the Indian Government Council." There are no such offices. If the cause of malarious fever is—as the *British Medical Journal* asserts it is—an animal parasite living in the blood, even then our profession in India does not deserve the hard things that have been said about it in view of the many members of the profession whose work and writings stamp them as ardent searchers after truth on plasmodist lines; but if, on the other hand, malarious fever is not due to a parasite in the blood, a *fortiori* if it is not primarily a blood disease, the *British Medical Journal* stands discredited in its self-imposed task of regenerating the medical services of this country, and we may reasonably demand to be left alone and to be allowed to manage our own affairs, sanitary or otherwise, in future.

[Surgeon-Lieutenant-Colonel Lawrie here exhibited a patient from Hyderabad suffering from enlargement of the spleen and malarious fever.]

The patient was admitted into the Afzul Gunj Hospital on Feb. 1st, 1896. Four months before admission he had fever daily, sometimes with and sometimes without ague; after twenty days he took quinine and recovered; six weeks later the fever returned, and he has had it off and on ever since. At times it is regular quotidian and at others it is irregular and of no pronounced type. Since he has been in hospital he has had fever for forty-two days out of fifty. Between Feb. 1st and 15th the fever gradually decreased from 105° to 99° F., with four complete intermissions. For the next nine days it did not go above 99°. On Feb. 25th it came on again with ague and has continued up to date. The spleen is tender and enlarged and can be felt below the left costal arch. His temperature has been taken every hour in the rectum: his blood has been examined every day under the microscope, and he has had no quinine. The point to which I desire to call attention is the condition of the patient's blood. Laveran's bodies have been found at every microscopic examination, and the black line on the temperature chart indicates very roughly the proportion of these bodies found daily. At a glance it can be seen that their number does not bear any constant relation to the temperature. It must be clearly understood that by Laveran's bodies are meant all those genuine abnormal cells found in the blood in cases of fever produced by malaria, and not such cells as are depicted in the pictures of THE LANCET and the *British Medical Journal* of Feb. 15th, 1896. These are not correct representations of Laveran's bodies. Some of them appear to be drawn from the imagination; others, especially the rosette forms, are caricatures of vacuoles and crenating or disintegrating blood cells. [Surgeon-Lieutenant-Colonel Lawrie here exhibited an enlargement of the drawings which had been made by one of his students, and compared them with the drawings from life of Laveran's bodies.]

In the pictures from THE LANCET and the *British Medical Journal* the representations of the three different varieties of "parasite," the quotidian, tertian, and quartan, of the first part of the first day are all exactly alike. The pictures of the "parasites" of the second part of the first day and of the second, third, and fourth days might be anything. Most probably they are crenating red cells. It is not stated whether the drawings of the "parasites" of the second, third, and fourth days are intended to represent one and the same body in different phases of its existence, or whether they are pictures of bodies seen at different times and assumed to be one body in different stages. Whatever they are, with one exception none of them are correct representations of Laveran's bodies any more than the picture I now show you of the man with his arms and legs extended is. This is taken from Marchiafava's book, Plate 2, Fig. 6, and it discredits the whole of the drawings in that work. No one who has studied Laveran's bodies could pretend for a moment that they ever take such a form as this. The only drawing in THE LANCET and the *British Medical Journal* series which is really at all like a Laveran's body is the crescent in line B, and even in this the granules are depicted in the wrong place. They are never situated as they are in this drawing, on one side of the cell only. All the drawings in THE LANCET and *British Medical Journal* are stated to be copies from the plates in Marchiafava's and Mannaberg's book, and I am not aware that Marchiafava or Mannaberg or Golgi ("the talented Italian" of that devoted worshipper of parasites and foreigners, Dr. Patrick Manson), or Bignami or Celli, or Gassi, or Felletti, or any of the Italian observers have any claim to confidence which can weigh for a moment against the established claims of the great and immortal

Digitized by Google

irchow and Frerichs, who failed to discover the parasite in alarial blood, or that they have any claim at all except at which is founded on their description and pictures of gus parasites of malaria.

It is not surprising that the theories of malarious fevers unded on the assumption that Laveran's bodies are animal arasites living in the blood are fantastic and fine-spun. verything, the very nomenclature of malarious fever, has een disturbed and recast by the clinical plasmodists in rder to meet the new pathology, "The Scientific Medicine" f the *British Medical Journal*, based upon a parasite of alaria, distorted and multiplied according to the exuberance f the successful observer's fancy. The fever produced by alaria is assumed to be due to: (*a*) the act of sporula-on of Laveran's bodies at intervals which are stated correspond precisely with the periodicity of the ver; or (*b*) to a poison given off by Laveran's bodies the time of sporulation. No evidence has been lduced in support of the theory that Laveran's bodies porulate, or if they do that the act of sporulation is eriodic, or that it is accompanied by the emission of any oison. The periodicity of the fevers of malaria has been onveniently assumed to bear an intimate relation to the appositious act of sporulation, and obvious inconsistencies ave been got rid of by the introduction of such terms as mixed infection," where two or three generations of arasites are presumed to be at work in the blood together, r "pernicious infection," in which the parasite is so deadly hat it kills the patient before it has time to sporulate or to o anything else but capture and penetrate the red cell. The ld term "quotidian," which still, I hope, conveys an ntelligible and practical meaning to everyone, has been iven a new interpretation, so that it no longer signifies an ntermittent but a continued fever.

The anæmia of malarious fever is considered by the clinical lasmodists to be due to the destruction of the red cells y Laveran's bodies, which devour them or eat them up, or some other plausible way demolish them. The excre-entitious products of the parasites in the blood and the orpses of those that die there in harness are further assumed y the plasmodist to be got rid of by the phagocytosis of the hite blood-cells or of the macrophages—the large nucleated ells of the spleen—or by the phagocytosis of the endo-helial cells of the bone marrow and of the cerebral blood-essels. Lastly, all this microscopic mass of excrement and f Laveran's defunct bodies has to be got rid of; and it is ssumed, in a most amusing way, that the phagocytes and nacrophages throw it out in the spleen, which must be, ccording to the plasmodists, a mere dust-hole, where it ccumulates until it gives rise to the enlargement of that rgan characteristic of malaria. For scientific medicine the hapter on Phagocytosis in Mannaberg is one of the most musing in the book. It ends with a hint that the useful-ess of the macrophages is at times marred to some extent ecause they occasionally over-eat themselves so tremen-ously that they burst and let all the spores they have evoured loose again before they have had time to digest hem. Time compels me to pass on; I must therefore leave he picture of the disappointed macrophage, all his obliging ndeavours to benefit the patient rendered nugatory by his wn amiable and well-intended greediness.

The bodies we have found in this patient's blood consist f: (*a*) intracorpuscular cells containing dark pigment-like ranules; (*b*) extracorpuscular cells also containing darkly igmented granules, sometimes "swarming" and occasionally eveloping ciliary or flagellated pseudopods (flagella); c) free granules, occasionally "swarming"; and (*d*) semi-unar or spindle-shaped bodies called crescents. These odies are different or varying phases of one and the same ell. The intracorpuscular body or cell becomes the extra-orpuscular body by bursting through or incorporating with tself the envelope of the parent cell. The crescent, the novement called "swarming," and the development of lagella are readily accounted for without the necessity of egarding Laveran's bodies as parasites in the blood. Before roceeding to consider in detail the exact nature of Laveran's odies and in order to facilitate the study of their meaning t is necessary to dwell for a moment on facts which are nown and which I have observed with regard to the hysiology of the blood. It is because these facts have een lost sight of or disregarded that the parasite theory of alarial fever has flourished to the almost inconceivable xtent it has. The physiological and biological state-ents I am about to make are gathered principally from Lister, Pettigrew, Landois and Stirling, and Drummond, supplemented by observations we have made in Hyderabad. If these observations are occasionally strongly stated it is because I wish to emphasise the lines on which I consider investigation should proceed in future and not because I wish to force other people to accept them. Healthy blood contains two kinds of cells, the red and the white. The red cells convey gases to and fro between the lungs and the tissues. Their functions are urgent and all-important and admit of no interruption or relaxation. Hence, among other marvellous qualities, they possess an elasticity which is absolutely perfect; nothing stops their career, and they dash through the narrowest channels, round the sharpest corners, and past obstacles of any and every kind without the smallest check or hindrance. The mobility, energy, and outward activity of the red cell give it the stamp of what Drummond calls "maleness"; it is an organism principally concerned with nutrition. The white cells are very different from the red. When fully developed they appear to me to be filled with granules which are minute living protoplasmic cells, and many of them contain large clear spaces, hitherto regarded as nuclei, which must, in my opinion, either be fertilising or nutrient areas; most likely they hold reserves of protoplasm, I throw it out as a hint to the profession that they supply the blood and all the tissues each with the particular kind of protoplasm and young protoplasmic cells suitable for its own special requirements. They incorporate in their own being the two main activities of all living things, nutrition and reproduction, and their internal activity or passivity and the fact that they teem with young cells and granules indicate that they are the female, in the sense of being the maternal, cells of the blood. The white cells are never in a hurry like the red; they loiter about in the capillary system and stick to the walls of vessels and pass through them, shedding their contents either in the blood or in the tissues. The white cells have special movements of their own, which consist of varied activities of their protoplasm. These cause the cell itself to change its shape and position, and they produce intracellular movements of the granular contents which are seen sometimes moving slowly and at others actively "swarming" with the identical movement described by Laveran in connexion with his malaria bodies as that of the "disturbance of boiling water." The white cells of the blood further have the power of throwing out pseudopods, processes which, if threadlike or filamentous, are called cilia or flagella, and these protoplasmic offshoots can be detached and lead for a time an independent existence. The ordinary forces of the circulation—the heart and the elasticity of the vessels—are not sufficient to account for the whole of the movement of the blood in the capillaries, and it seems, therefore, highly probable that both the intracellular circulation called "swarming" and the evolution of "pseudopods," which is a primitive force of the circulation, are what Pettigrew long ago described as those occult forces which regularly assist in the peculiar circulation of the blood-cells and of the blood-plasms in the capillary system.

A most important point bearing on the origin of Laveran's bodies is the source from which the blood-cells are derived. They are largely manufactured or elaborated in the spleen or liver. In man the red cell is not nucleated, but in the human embryo it is nucleated, and it is also nucleated in the frog, and in the frog the nucleus is clearly the intracorpuscular stage of the white cell. Fig. 1 shows a red and a white cell of frog's blood copied from Landois and Stirling's book, and it is evident that the white cell is identical with the nucleus of the red. I was led to make an examination of the blood of the frog by an accident. In accordance with letter No. 3278 from the Government of India Foreign Department to the Resident at Hyderabad, covering a paper by Dr. Patrick Manson on the Nature and Significance of the Crescentic and Flagellated Organisms in Malarial Blood, the medical officers serving under the orders of the Resident at Hyderabad were directed to make observations on the "organisms of malaria," and were specially enjoined to pay particular attention to the life history of the "parasite." At the time this letter was received in my office we had been working for several months at the microscopic appearances of the blood in malaria, and it appeared to me that before Laveran's bodies could be properly assumed to be parasites they must be shown to have an independent existence outside the human body, and that a likely *habitat* for them if they had such an existence would be the body or the blood of frogs, frogs being known to flourish where

malaria abounds. The examination of the blood and of the liver and spleen of frogs was undertaken while the animals were alive (anæsthetised). In the blood and in the free protoplasm of the liver and spleen we discovered, to our astonishment, not Laveran's bodies, but their perfect and complete analogues. In the liver and spleen of frogs were found small protoplasmic cells and granules identical with those contained in the white blood-cells in man, "swarming" with the same movement of boiling water which Laveran had discovered in his organisms and which we had discovered in the leucocyte. We also found blood-cells in every stage of development, and the white cell could be traced from its origin as an intracorpuscular body, when it sometimes becomes the nucleus of the red cell and at others becomes a free and independent leucocyte, until it changes into an extra-corpuscular body by bursting through and incorporating with itself the red cell. The white cell in the frog has to serve the purpose of nutrition of a simple, slow, cold-blooded amphibious animal and the processes of its development are correspondingly simple and easy to follow. In man the blood cells are unquestionably formed on the same lines as those of the frog, but the nutritive processes are so complex and the difficulties of examining the blood glands during life are so insuperable that it is correspondingly difficult to follow the stages of the developmental processes. It is a curious fact, however, that wherever difficulty arises in tracing out the analogy between the two assistance is afforded by Laveran's bodies. Lastly, the "swarming" movement of the protoplasm and of the young protoplasmic cells in the spleen of the frog indicates that there is a double circulation in that organ and very probably in the liver also. This view receives confirmation from the discovery of Roy, extended by Schäfer and Moore, of the rhythmic contractility of the spleen. I mention this here because the double circulation in the spleen may turn out to have an interest bearing on the diurnal variations of the temperature in health as well as on the periodicity of malarious fever when those variations are exaggerated.

In the light of the above physiological facts we are in a position to consider the actual value of the characteristic features of Laveran's bodies which have been made the foundation for the belief that they are parasites living in the blood. 1. They are intracorpuscular in one stage of their existence. But the white cells of the frog's blood, which are the analogue of the human white blood cell, are at one period of their existence intracorpuscular bodies and no one would dream of calling them parasites. 2. Laveran's bodies are at another stage of their life extracorpuscular. So are the white cells of the blood. 3. The free body changes its shape and becomes oval or crescent-shaped (Fig. 6). The crescent is supposed to be a parasite and to "devour" the red blood cells. There is nothing remarkable about the change of shape of the crescent. All cells which contain granules tend to become spindle-shaped when the granules collect in the centre of the cell and round again when they spread out to the margin, and the red blood cell of the frog in which the granules of the nucleus are collected in a compact mass in the centre is itself spindle-shaped. The resemblance between the red blood cell of the frog and the crescent is so marked, especially when the latter is changing its shape, that it cannot be accidental. The true semilunar shape which the crescent assumes is certainly very curious and interesting, but it only takes this shape when the granules are collected quite in the centre, and the cell is consequently very markedly spindle-shaped, as a mechanical result of the force of the blood current. If you apply the methylene blue stain to a preparation of fresh blood, first to one side of the cover-slip and then to the other, so as to create currents in opposite directions, you can make the crescent semilunar in either direction in which the ends are wafted by the current created by the stain. 4. The granules in Laveran's bodies occasionally undergo a "swarming" movement which Laveran compared to "the disturbances of boiling water." The same movement was discovered by us in the normal human leucocyte and it can readily be produced artificially. The importance of this "swarming" movement cannot be over-estimated (Figs. 2, 4, 5, 7, 8, and 9). From the moment when we found swarming in the leucocyte it became clear that Laveran's bodies and the white cells are closely allied and that one is no more likely to be a parasite than the other. "Swarming" is confessedly one of the most characteristic attributes of Laveran's bodies; it is a sign of life. The "swarming" movement, therefore—the "boiling water movement" of Laveran—on which the plasmodists rely most confidently for the identification of Laveran's bodies as parasites, if it is conclusive evidence of anything, is merely evidence that they are related to the white cell. The proof is clinched by the discovery of the same swarming movement in the normal protoplasmic cells and granules in the liver and spleen of frogs. The same thing may be said with regard to the development of cilia or flagella in connexion with Laveran's bodies. In view of the elementary truth that ciliary and flagellate varieties of pseudopods are known to be present and to constitute normal forces in the circulation in plants and animals, there does not appear to be any reason why they should be described as signs of parasite life only when they occur in connexion with Laveran's bodies in the fever blood of malaria.

We now see that none of the qualities of Laveran's bodies warrant the assumption that they are parasites; on the contrary, they have their complete analogues in the cells of the blood both of man and of animals; moreover, they are not present in the blood in a considerable proportion of cases of malarious fever of the most fatal and chronic types. They cannot, therefore, be the cause of the fever. If Laveran's bodies were the cause of the fever in malaria the plasmodists would surely have been able before now to isolate them in pure culture and to demonstrate their existence outside the human body. Dr. Patrick Manson states that "the intravenous injection of blood containing this parasite into a healthy individual is followed by the multiplication of the parasite in the blood of the person inoculated, and also by the occurrence of the characteristic fever." There can be no justification for employing intravenous injections of malarial blood in the human subject, but during our investigation we did employ them repeatedly in dogs and in monkeys. When they produced any effect at all it was to give rise to a sharp attack of fever which passed off on the same day, and was not accompanied by the formation, much less by the multiplication, of Laveran's bodies in the blood. According to my experience, which is, however, confined to cholera cases, the intravenous injections of healthy blood or of saline fluid produce similar effects in man. They give rise to ague and fevers, but the symptoms so produced by the saline fluid are most assuredly not malarial. From an examination of a very large number of spleens and livers of frogs, which are always healthy, we have come to the conclusion that frogs are immune against malaria. We therefore fed one of our fever patients for several days on the spleens and livers of frogs and gave him daily subcutaneous injections of frog's serum. This treatment had no effect in arresting the attacks of fever, as it might have been expected to have had if the cause of the disease had been (*a*) a parasite in the blood against which the frog is immune, or (*b*) a defect in the spleen of the same nature as those defects of the thyroid gland which produce diseases which can be remedied by thyroid feeding.

Enough has been said to show that Laveran's bodies are not animal parasites living in the blood. We have dealt with three forms of blood cells: (*a*) those of the frog, in which development is slow and easy to follow; (*b*) those of the healthy human subject, in which development is so rapid that it is difficult to trace except in the way of analogy with the frog; and (*c*) those of the malarious human subject Laveran's bodies which are diseased or degenerate, but in which the development is not so rapid as in the healthy human blood cells, and in which the analogy to normal human blood cells on the one hand, and to frog's blood cells on the other, can be traced without difficulty. A study of Laveran's bodies renders many points in the physiology of the blood clear and distinct. Thus their intracorpuscular stage indicates that the human white blood cell begins life as an intracorpuscular body. The extracorpuscular stage is synonymous with the free and independent existence of the leucocyte. The crescents indicate the spindle shape of the red cells, which is normal in the frog and other lower animals, and the swarming movement and the development of ciliary or flagellate pseudopods afford strong presumptive evidence that the circulatory forces, which are recognised conditions of the circulation in animals and plants, are regularly at work in the capillary system of man. It only remains to state or reaffirm the source of origin of Laveran's bodies and to consider the theories of malarious fever based upon it to the extent to which it is warranted by actual facts. The spleen is undoubtedly the organ mainly concerned in the production or elaboration of the white blood cells, though other blood

Explanatory note on the figures of blood cells and of Laveran's bodies.—The term "Laveran's bodies" has been employed for convenience without reference to the school which claims to have discovered them. The striking points in the above groups of blood cells are: (*a*) the resemblance between the white cell and the nucleus of the red cell of the frog's blood; (*b*) the resemblance between the red blood cell of the frog and the crescent; (*c*) "swarming" was seen in Figs. 2, 4, 5, 7, 8, and 9; and (*d*) in Figs. 8 and 9 the cells are only partially diseased—in Fig. 8 the cell contained a number of healthy protoplasmic cellules, such as are seen in the healthy leucocyte, along with the usual black pigment-like granules which are met with in Laveran's bodies; and in Fig. 9 the cell contains a clear nuclear space like the nuclear spaces in the leucocyte.

glands may assist in the process. We have just seen that the analogy between Laveran's bodies and human blood-cells as well as those of the frog which are manufactured in the liver and spleen is close and absolute, and in the third place the spleen is invariably diseased in malarious poisoning. From the three facts it is evident that the Laveran's bodies are merely the kind of degenerate blood cells which are turned out by the spleen when it is dragged down from its high pinnacle of evolution by malaria. (Figs.'8 and 9.) The precise manner in which malaria acts upon the spleen can only be determined by future observation. All we know at present is that in certain localities and climates which we call malarious enlargement of the spleen with fever and anæmia is endemic, just as we know that in other localities and climates enlargement of the thyroid gland with bronchocele and various constitutional symptoms, and in others again stone in the bladder, are endemic. Our theory of malarial fever, then, is that it is produced by the action of malaria on the spleen and that the production of Laveran's bodies, which are not found in anything like all cases of malarial fever, is one of the effects of the distempered condition of the spleen of splenitis. Several facts point irresistibly to this conclusion; for instance, congestion of the spleen, characterised by enlargement or tenderness, or both, is the most constant of all the symptoms of malarious poisoning. Secondly, it is the sign on which reliance may most safely be placed in making the diagnosis of the malarial origin of fever, and if it is not present it is generally well to consider the advisability of excluding malaria as the cause. In the third place the only drug which can be trusted to cure enlargement of the spleen from malaria and the fever which springs from it is quinine, and it restores equally those cases in which Laveran's bodies are and those in which they are not found in the blood. Lastly, when Laveran's bodies are present they attest in terms which are unmistakable that the spleen is the organ primarily affected by malaria. The first effect of malaria on the spleen is to disorder its functions, and the patient gets fever, sometimes markedly periodic and sometimes not. It must not be forgotten that the temperature of the blood in health shows regular diurnal variations between 97° and 99° F., which depend to a large extent upon the periodic nocturnal inactivity and the diurnal activity of the spleen. The periodic attacks of fever are amply accounted for by the view that they are exaggerations of the diurnal activity of the spleen. The disturbance of its functions may cause the diurnal variations to be exaggerated daily, quotidian ague, or every alternate day, tertian ague, or every third day, quartan ague. As the disorder of the spleen increases its functions of regulating the diurnal variations of temperature become less clearly pronounced, they are, as it were, lost in the disease, and as a consequence the attacks of fever seldom maintain periodic regularity for any length of time and they become irregular. If the irritation of the spleen is very great, or if it is accompanied by derangement of important organs like the brain, the liver, the stomach, or the bowels, the fever may be irregular or continuous from the onset. As the disease progresses the spleen is no longer able to elaborate its full complement of perfect white cells. It manufactures a certain number of imperfectly developed or abnormal cells, which pass into the blood, and these are Laveran's bodies. The symptoms produced by the presence of these bodies in the blood are easy to understand: they are symptoms of disordered nutrition. Instead of receiving their normal supply of life-giving white cells all the tissues of the body get a proportion of Laveran's barren, innutritious, and not unfrequently lifeless organisms. It is not surprising that a patient who has malarial fever is generally pale and has headache or perhaps severe cerebral symptoms, with indigestion, constipation, and derangement of the liver, or that he feels very ill and becomes thin; the nutrition of every tissue and organ in the body suffers. Finally, when the enlargement of the spleen becomes, as we say, chronic, its functions as a blood-forming organ are entirely in abeyance; even the degenerate cells of Laveran are no longer produced, and the anæmia becomes permanent and profound.

Such is a brief outline of our theory of the action of malaria. We claim for it that it confirms the principles on which our predecessors, who were by no means the ignoramuses they have been made out to be, practised successfully in India. It explains as no other theory will the phenomena associated with acute and chronic malarious fever, and it suggests a long vista of possibilities as regards the action of the spleen and the reaction of the tissues on the blood in such conditions as inflammation, gangrene, septicæmia, leucocythæmia, and anæmia generally. Moreover, it is the only theory which accounts satisfactorily for the action of quinine in enlargement of the spleen and malarious fever. Quinine acts directly as a specific on the diseased spleen and through it on the white cells of the blood, and this teaches us not only its effect in curing malaria, but also its unique action as a tonic and its prophylactic action against cholera and other infectious diseases when they are epidemic.

THE EVOLUTION OF THE SURGICAL TREATMENT OF THE BROAD LIGAMENT PEDICLE.

BY LAWSON TAIT, F.R.C.S. ENG.

A VOLUME which I published in 1891 was devoted mainly to the establishment of severe operative procedures for the relief of diseases of the pelvis and abdomen, especially in women. It dealt chiefly with the leading features of these proceedings in the direction of reducing their primary mortality and establishing them on the basis of giving a reasonable return for the risks run. This in every instance has now been fully accomplished, and if I had confined myself to such themes in my first volume my second would have been ready long ago; but the appearance of the first effort towards the latter has been delayed till to-day, for I have found so much to reconsider in the second division of my task that I have had to decide to wait over and over again till the effort seemed to me to be hopeless, and I felt at last that I should leave it to other hands to accomplish. In the intervening six years the field of surgical literature has been flooded with contributions to abdominal surgery, some good, a few very good, very many indifferent, and the great bulk hardly worth notice. I have waited to see if anyone would take up what seems to me to be the logical method of advance, but I have found none; and the effort which I now begin to-day to produce my second volume and to indicate the lines on which I have improved and still hope to improve the secondary results of our operations may turn out to be a failure as great as any which I have just deprecated. If, however, it have anything like the success which my first volume has met with I shall be pleased indeed, and, in my own opinion, the second will greatly transcend the first alike in interest and importance.

As the whole history of abdominal surgery, in the slow and tardy evolution of its first stages, turned on the treatment of the broad ligament pedicle, so my first efforts in the secondary evolution necessarily start at the same point, and it is, to say the least of it, disappointing to me to see how little the importance of this subject has taken hold of the men who have written most fluently on abdominal surgery and who have brought out the most popular text-books. Mr. Greig Smith's book, for instance, will to its ordinary reader seem sufficiently imbued with my own teachings, yet he says concerning the treatment of the pedicle: "It has always seemed to me that this *quæstio vexata* of ovariotomy has been unduly magnified in its importance. To a surgeon accustomed to deal with amputated limbs the pedicle is comparatively a small matter." If this is the view generally of surgeons accustomed to deal with amputated limbs I hope fervently that no one in whom I have any personal interest will ever fall into their hands for the treatment of an ovarian tumour. Coming from the pen of a man like Mr. Greig Smith it can only mean that while he has written freely and with confidence he has not seen enough ovariotomies to know how wholly different these pedicles can be, and that his comparison of them with the symmetrical and constant incidents of amputated limbs is the most perfect nonsense. Similarly, the experience of one or two cases where chronically overdistended bladders had been tapped for ovarian cysts, or even attempts made to remove them by abdominal sections, will some day cause him to repent bitterly of the following sentences: "I think that the advantages of catheterism before operation are somewhat exaggerated. I am convinced that it is unnecessary and I have never done it." From

Digitized by Google

hese illustrations I am persuaded that the creation of abdominal surgery into a special branch of surgery was a rise movement, on the same ground that the development of ophthalmic surgery has upset the advice we used to find in a ew chapters on diseases of the eye—oddly enough, placed at he end of text-books on practice of medicine—that in all ases of strabismus the muscles supposed to be at fault were o be freely divided. It may be useful on one other point to ontinue my criticism of Mr. Greig Smith's text-book, and hat is his expression of opinion that "the operation of Houston of Glasgow (1701) was almost certainly not a com-lete ovariotomy." But apart from the very conclusive fact hat the patient lived afterwards in perfect health for hirteen years—not known in my own experience of in-omplete ovariotomies—Mr. Greig Smith only lays himself pen again to a charge of defective experience. I could not nderstand why Houston should describe his proceedings with such photographic fidelity of detail and say nothing bout his treatment of the pedicle, and I assumed that he nust have divided and tied it and forgotten to mention the act. I did not attach sufficient importance to the fact that Houston had met with one of those singular eccentricities of varian growth with which my own long list is interspersed with a goodly number, and it was not till I began to dig hem out and carefully investigate their details that I saw he probability of Houston's description being perfect even n the absence of allusion to the pedicle and its treatment. The clue is in his words: "I took a strong fir splinter, such s the poor in that country use to burn instead of candles; I wrapped about the end of this splinter some loose lint and hrust it into the wound, and by turning and turning and winding it I drew out about two yards in length of a sub-tance thicker than any jelly, or rather like glue fresh made nd hung out to dry; its breadth was about ten inches. This was followed by ..... several large pieces of membrane which seemed to be parts of the distended ovary. I then squeezed out all I could and stitched up the wound," &c.

When I got a group of my own cases together it was easy o see that Houston's belonged to them, and that they form a group by themselves, having peculiarities of their own, not he least curious of which is the fact that they probably present the examples which occur beyond all doubt of varian tumours undergoing spontaneous cure—examples, owever, so rare that they may be certainly disregarded in ny discussion of treatment. These cases have all the same haracter, and no description can be better than that of Houston's own experience. The cyst-walls are always thin, nd so far as my memory and my notes serve me the tumours re sessile. In three well-marked and entirely similar cases he cyst-walls had given way and the gluey contents were iffused throughout the abdomen. The cyst-walls, or rather heir remains, were isolated by washing out and were then ound to be mere shreds, patches and strings of membrane with attached masses of cystic proliferation, by which only heir inner surfaces could be recognised. These shreds and atches were quite rotten and came away from their very ague attachment in the pelvis on slight touch, and no liga-ures were necessary. In all three drainage-tubes were left n at the close of the operation, and large quantities of the gluey material, more or less in solution, were discharged for ome days. My belief is that in none of these three cases vas the operation really necessary. Had I left them alone he gluey material would have been slowly absorbed and the hreds and patches would have contracted and disappeared nless they had developed malignant tendencies, and there is a suspicion that this did happen afterwards in one of my ases. This is a secondary termination from the risk of which no ovariotomy is free. These three cases are, there-ore, precisely on a level with Houston's, only that I did a little more scientifically and with better tools what he did s effectively with a bit of stick. What is the explanation f them? That question I can only answer by speculation. True pedicle they have none, and it seems to me as if, and t a certain point, the cyst contents have a digestive power ver the cyst walls, and that in time the peritoneal surfaces igest the cyst contents. It may be that when we come to he base of the tumour and pull away the rotten remains we omplete the process by a rough enucleation, but I cannot eally say I saw the base of attachment of these three umours, and Houston did not see his, therefore he said nothing about it; but I saw mine with the eyes of the blind, nd only at my next experience will my eyes be open enough o get a true record of the state of matters. Meantime I ave said of Houston that the earliest known treatment of the ovarian pedicle was probably enucleation. Houston's operation makes a most interesting and picturesque addition to the early history of abdominal surgery, but it has no value at all, although it was published in the stately Transactions of the Royal Society of London, which were read then as now with avidity all over the world. He found no imitators. The first really deliberate and systematic attempt to do serious operations for abdominal disease was that of Ephraim McDowell. McDowell's method of dealing with the pedicle was what he had learned from John Bell in Edinburgh, and which was applied to all arteries and to everything containing an artery down to my own time — the long ligature. In a stump the arteries were tied with a hempen ligature, one end was cut short and the other left long, the series to decorate the suppurating stump for many days, the amusement of the house surgeon and the terror of the patient being their removal by tugging as soon as they would come. Often they never came. How it did not strike someone to try how they would do if both ends were cut short I cannot imagine. But the difficulty set Simpson's ingenious mind to work with his visionary acupressure, and he unconsciously cleared out the long ligature. How the short ligature came into use in general surgery I do not know. In ovariotomy it appeared early in the history, but most unfortunately only for a short time.

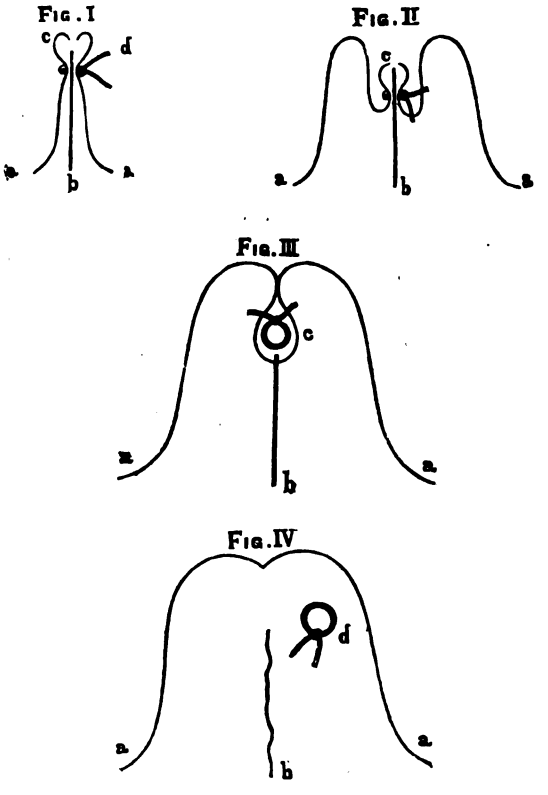
In 1822 Nathan Smith of New Haven, Connecticut, did his first case with the short ligature, dropping the pedicle in, and he followed this by a series of cases so successful that it must ever be the amazement of future historians of surgery how his example was not at once followed. His lesson was far more valuable than McDowell's and his action more philosophical, for he argued out the necessity for the short ligature, and he used animal ligatures (pieces of kid glove), in the belief that they would be absorbed—a conclusion most abundantly proved to be correct. His lessons were neglected, for his statements were widely published here, yet the long ligature held sway till the advent of Baker Brown in 1851. He in turn introduced the treatment of the pedicle by the cautery, gaining his idea doubtless from veterinary surgery. A most unfortunate incident occurred soon after this by the invention and introduction of the clamp treatment of the broad ligament pedicle—an incident, according to his own authority, to be laid at the door of Mr. Jonathan Hutchinson. The short ligament was reintroduced and reinstalled almost simultaneously in 1878 by Bantock and myself and has since remained the only method of dealing with the broad ligament pedicle except the cautery and clamp used by Keith to the last. Up to that time we were all astray except Keith, as we used Hutchinson's clamp with varying mortalities, running between the dreadful limits of 25 per cent. and 50 per cent.; Keith alone adhering to Baker Brown's method brought down his mortality and swept the world with his brilliant success. Very soon, however, Keith's record was beaten by the ligature and then it became manifest that the main principle to be followed for success was that of the intraperitoneal replacement of the divided and secured pedicle, and that there was little to choose, so far as promising results were concerned, between the cautery and the short silk ligature. As I watched Keith operate in 1880–81 I became convinced that the cautery was the ideal method of pedicle treatment, but for the tremendous time it occupied and the large amount of physical exertion involved. Keith and I agreed to stick each to his method and after a long series of cases to compare results. But Keith ceased to publish under conditions which made comparison possible and the contrast has never been made. I do not, however, think any other conclusions than those I have indicated could ever have been derived. I have, however, been haunted ever since by the clear, thin line of parchment to which Keith reduced his pedicles, and I have looked at my own, often regretting the dead lump of wet and decomposable tissue I had to leave, girt by a dead and decomposable ligature. But still it is certain that the great bulk of these difficulties were successfully encountered by that wonderful power which living tissue has for removing dead matter, a power for which so many theories have been advanced of late years without leading us much beyond the facts.

I have not yet seen a case in which post-mortem examination made it evident that death was due to the ligature, though I have seen several—some amongst my own cases, I regret to say—where faulty application of the ligature has been the cause of death. If the ligature is so applied that

Digitized by Google

it controls hæmorrhage completely the ligature does not contribute in any way, so far as I know, directly or indirectly, to death. But it has a most unfortunate way of contributing to secondary failure, to incomplete cure, and to persistent and vexatious interference with convalescence. The first of the instances of this kind as being never fatal, but as being the more common and more alarming of the two to be mentioned, is the occurrence of broad ligament hæmatocele. Speaking to Keith about this his answers impressed me with the belief that the accident did not occur in his practice, and he was far too shrewd and anxious an observer to miss it if it had occurred frequently. The users of the clamp certainly did not place its occurrence on record; but with a mortality of 25 per cent. raging round them it is not likely that they would observe it if it did occur; and where it occurred I think death must have been inevitable. I cannot imagine any more certainly fatal combination than a broad ligament hæmatocele and a stinking stump. But still the question stares us in the face, Does the ligature cause or facilitate the occurrence of broad ligament effusion? I confess I strongly suspect that it does, and this is one of the reasons of my present paper. The second incident which tells against the ligature is the occurrence of a number of cases, 3 or 4 per cent., in which the garrotted stump and ligature get the better apparently of the living tissue around them, prevent the tissues absorbing them, cause suppuration, form sinuses which do not heal, but go on discharging till the knot of thread is got rid of, months, it may be years, after the original operation. Sometimes they burrow into sinuses of the broad ligament and are discharged into the rectum and bladder. Quite a group of these latter cases has now occurred where I have removed knots of thread from the bladder contained within a thick deposit of phosphates, some of the ligatures having been originally placed by myself and some by others. How these ligatures travel in this way is a matter of easy explanation, and that is, I think, as follows. Suppose the ligature is placed on the right pedicle it will go (as a matter of fact, three of my own have so travelled) into the bladder, whilst if it be a left broad ligament pedicle to which the ligature has been applied it will more likely get into the rectum. In fact, as I have often had occasion to observe in operating for pelvic abscesses, the bladder seems the road out of the right broad ligament, and unquestionably the rectum is the point of election for the natural evacuation of the left parametric cavity.

The method of inclusion of the ligature is curious and interesting, for it seems difficult to imagine at first sight that a ligature tied inside the peritoneum would, as a matter of course under certain conditions, work its way through that membrane and into an extra-peritoneal district. It happens thus. The ligature (Fig. I., *d*) is tethered to the floor of the pelvis by the vessels and nerves it embraces. The peritoneum (*a*) is raised up and round it and finally over it by the effusion of blood, until a tube of inverted peritoneum (*c*) is made with the ligature at the base (Figs. II. and III.). The mouth of this inverted tube is closed by adhesion at its intra-peritoneal end and opened at the ligature end by the subsequent suppuration, and the loosened ligature drops into the increasing and purulent cavity of the broad ligament (Fig. IV., *b*). Its subsequent journey is a matter of notoriety and of long and protracted suffering for the patient. I could, unfortunately, point to a number of my patients who have been for months and even years undergoing this torture from what I call "a dead ligature." I have made various attempts to relieve them, some I am glad to say successfully, and others I regret to say with failure. But they will get well in time, and none, so far as I know, have died in the process. But for these two reasons I want to get away from the ligature if I can, and after years of experimenting and thought I think I have at last succeeded. But the difficulties have been so great that I have not yet ventured to apply my plan to a living subject. Fortunately, however, for my consistency dead animal tissue is helping me thoroughly, and experiments on animals are unnecessary—for this purpose at least. My constant feeling has been that in the cautery we should find the solution of the difficulty, and it really shows how careful we ought to be in all our experiments in surgery, that it was not till after at least two years' consideration of the subject that it dawned on me that we did not understand how the cautery really works. I do not think that either Baker Brown or Keith understood how they arrived at their certain and magnificent results. I am sure the bystanders did not. Everyone whom I have asked questions has answered: "Oh, yes, sear the stump; barbarous practice, going back to the days before Ambrose Paré." But Keith did not sear the stump. It is true he burnt a piece of it off after securing it with Baker Brown's clamp, and if searing had been the means of his success he would have stopped there. But he went on for about twenty minutes or half an hour rubbing the clamp with his cautery and clearing it with a towel or sponge until the onlookers got weary of the proceeding and thought Keith was finical. What he had done was really this—and I found it out only after much experimenting—that he had seized a transverse strip of the pedicle between the iron blades of his clamp, screwed the blades up tight, and then heated his blades up to cooking point—that is, practically between 180° and 190° F.—and carefully maintained that temperature till the enclosed strip of pedicle was cooked dry into a strip like parchment. Now Keith either did not understand what he was doing, but acted merely by rule of thumb, or he kept his real reason for using the cautery a profound secret. Had he seared the tissue the probability is that either hæmorrhage would have occurred soon after the patient recovered from shock or that the burnt mass would have caused pelvic suppuration—it would not have been absorbed. Having satisfied myself of the validity of this exclusion I set to work to contrive a better method of arriving at the same results, and after many failures I have found it in the method of cooking by electricity. Knowing the resistance of a certain piece of platinum wire I embedded it in a box of silver and isolated it by means of plaster-of-Paris, kaolin, or pipe-



clay. Two such boxes are placed face to face and connected by the necessary binding screws. The boxes are placed opposite each other on a pedicle and are screwed together. An electric current of known strength and under the control of a rheostat or a Kelvin's balance is now turned on to heat the boxes, or, better still, the boxes are heated first and then applied to the pedicle, as this method saves time. The boxes are enclosed in ivory or other bad conductor of heat, to save alike the heat and the tissues for which the heat is not wanted, though this precaution may be dispensed with. The apparatus I now describe will so cook an ordinary pedicle that hæmorrhage will be impossible and suppuration unlikely in the extremest degree in a space of about six to eight minutes. The contrivances shown are rough, but they

Digitized by Google

are in process of amendment, and the same principle is being applied to instruments for the arrest of visceral oozing and for parietal and omental hæmorrhage and for the simplification of the operation of total removal of the uterus. Also for operating on hæmorrhoids. I do not advocate my proposals as likely to reduce the primary mortality of operations, I believe that has been done so far as may humanly be possible. But I am quite sure that they or some others on similar lines will go far to secure our secondary results being more satisfactory and encouraging alike to our patients, ourselves, and to the art of surgery. I have no doubt the new electric hæmostat will find many fields of usefulness in general surgery.

The Crescent, Birmingham.

PERINEAL PRESSURE IN CYCLING.[1]

BY ARTHUR CHARLES ROPER, F.R.C.S. EDIN., M.R.C.S. ENG.,

CONSULTING SURGEON TO THE EXETER DISPENSARY; SURGEON TO THE DEVON AND EXETER HOSPITAL; AND ASSISTANT SURGEON TO THE WEST OF ENGLAND EYE INFIRMARY.

FOR the whole of last summer and for an uncertain number of antecedent cycling seasons I have noticed that when riding a cycle any considerable distance, and especially when riding at a good pace, I have found it necessary to dismount and urinate every hour or oftener, and this was obviously not on account of any increase in the amount of urine excreted. When doing this I have found the penis to be cold and shrunken and the scrotum in a similar condition. The return to a normal condition was often accompanied by considerable aching. There was usually a very slight difficulty in passing urine and a difficulty in getting rid of the last few drops, so that if one was unhappily hurried or disturbed in the final stage of this somewhat commonplace operation a familiar and uncomfortable trickle down the left thigh marked the fact that one was in a more or less senile condition. Another thing which I noticed or subsequently called to mind was that I had to micturate oftener than usual at night. I mean that, my usual habit being to empty my bladder before getting into bed and having no further occasion to pass urine before morning, I found that after riding I had to get up once or perhaps twice for this purpose. Many cyclists have complained to me of the foregoing symptoms and I am inclined to regard them as danger signals which should be regarded lest, as in my case, worse befall. In the beginning of last September I took a ride of about thirty miles and had to travel over some very rough roads. First came the frequent micturition trouble, followed by dull aching over the pubes, and by the time I reached home I was in a state of considerable discomfort and had much difficulty in passing urine and pain in the act. A hot bath relieved the retention, but I had to use a morphia suppository to cure the pain, and I was soon forced to the unpleasant diagnosis of cystitis, which I could not and cannot doubt was traumatic in its origin and was probably started by bruising and constant jarring of the bulbous portion of the urethra. To cut a long story short I had a most uncomfortable two months of it. The pain was at times so bad that I had to lie on my bed for an hour or two. I had the greatest difficulty in so arranging my work as to be certain of passing a public urinal every three-quarters of an hour or getting to a patient's house where I could lose myself in the W.C. on my way to or from the bedroom (it was astonishing to me to discover how closely those places are watched; I had never suspected it before); and as to medicines, boracic acid, salol, and benzoate of soda were worse than useless; citrate of potash with hyoscyamus and buchu were useful as palliatives, though uncertain; belladonna suppositories afforded by far the best relief from the strangury, but were of no use unless pushed to absolute dryness of the Schneiderian membrane; and the drug which cured me was arsenic, which my friend Mr. Bruce Clarke prescribed for me about the middle of November, though it was not until about Christmas that I ceased to find the call to micturate very urgent, albeit not unduly frequent. I found on three or four occasions when I was very bad that thoroughly washing out the bladder with hot water and boro-glyceride gave me a day's relief, but my urethra was so tender in front of the triangular ligament that I avoided that as far as possible, only doing it when my urine was alkaline and the mucus unusually abundant.

In order to show the mode of origin of these troubles I will first briefly refer to the anatomy of the perineum. It is a rough triangle, or, as anatomists prefer to call it, a lozenge-shaped space, bounded behind by the coccyx, the edges of the glutei muscles and sacro-sciatic ligament, and at the sides and apex by the pubic arch and symphysis. In the middle line from behind forwards are the rectum and the urethra with its bulb. On either side are the ischio-rectal fossæ, containing the nerves and bloodvessels which are distributed to the rectum and overlying skin, and which run forward to supply the penile and urethral muscles, and are finally distributed to the integument of the penis, scrotum, and perineum. The floor of the perineum is formed anteriorly of the unyielding triangular ligament, which is pierced by the urethra at its posterior part and nearer to the symphysis pubis by the dorsal vein and dorsal arteries and nerves. After the bulb it is with the nerves that we are most concerned, and they are—(1) the inferior pudendal, from the small sciatic, which pierces the fascia lata, curves forward and, running along the ramus of the pubis, is distributed to the skin of the scrotum; (2) the anterior and posterior superficial perineal from the pudic; (3) the muscular branches of the pudic to the transversus perinei, the accelerator urinæ, erector penis, and compressor urethræ muscles; and (4) the dorsal nerve of the penis, the terminal branch of the pudic, which perforates the triangular ligament behind the crus of the penis. We have then between the skin and the bone the inferior pudendal nerve, and between the skin and triangular ligament the bulb, urethra, and superficial perineal nerves, and the accelerator urinæ and erector penis muscles with their nerves. Obviously, then, anything which can exercise pressure between the sides of the pubic arch must compress these structures more or less against the bone and the unyielding triangular ligament, thus accounting by pressure on the sensory nerves of the part and on the motor nerves which supply the muscles of the urethra for the shrivelling and aching of the penis and inability to completely empty the urethra after micturating.

And now let us look at an ordinary bicycle saddle. Could anything be more deftly contrived to exercise this pressure? What is it but a modified wedge which becomes more and more operative as it is softened and stretched by use? Stretched by use! And when it is so stretched, is the modification in its shape a betterment or the reverse? The answer is unhesitatingly to be given, worse, far worse, for then we ride upon what is more or less of a strap, which shapes itself with painful accuracy to the perineal curve, while the concave form which it takes renders it practically impossible to sit back upon it and get good bearings for the ischial tuberosities. Let us for a moment turn our attention to its construction. It is mounted on a spring of some kind or other, or it is merely put on the machine without a spring, the resiliency of the pneumatic tyre sufficing for some riders. It is fixed at the peak only in front and behind by its whole posterior border to a steel plate called the cantle. It is unlike the equestrian saddle in not being supported in its whole length by a plate, technically the "tree." Its ground plan is roughly that of an isosceles triangle suspended between the apex and the base, a bridge, nay, a veritable "pons asinorum," and one that may claim to rival the "pons" invented by that terror of my youth, Euclid, in the amount of discomfort which it has caused.

Now, of course, the parts of our body which are specially adapted for sitting are the tuberosities of the ischium with their surrounding cushions of muscle and fat. It is, however, the bony parts which are intended to carry the weight, and it certainly is not intended that our ischio-rectal fossæ and the delicate structures of the perineum should carry the weight of the body upon a jarring or bumpy road. The transverse diameter of the outlet of the pelvis—i.e., the distance between the ischial tuberosities—is four inches, and at least one inch and a half must be added to this on either side if we are to derive the full benefit from our natural padding, and since we should not find it comfortable to sit on the steel base of our triangle we should have, if we use a suspension saddle, at least seven inches of suspended leather behind upon which to sit, exclusive of the steel cantle. But even supposing that we have a new saddle upon which we

[1] A paper read before the Devon and Exeter Medico-Chirurgical Society, Feb. 21st, 1896.

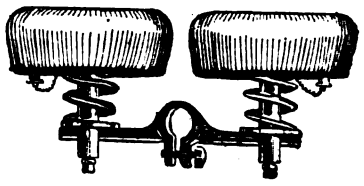
Digitized by Google

can sit comfortably upright with our tuberosities properly supported, what happens as soon as we begin to drive our machine? Our thigh straightens, our hamstring muscles contract and harden, &c., the edge of the saddle acting as a fulcrum, we are levered forwards until we come to that part of the saddle where no leverage obtains, which amounts to the same thing as that part of the saddle where our tuberosities have no firm bearing. This can be discovered in a moment if you will sit on a table and straighten your thighs. The action lifts you off the table. Thus, then, you are lifted on to the narrow part of the saddle and your body weight is transferred from the back to the peak of the saddle, from your tuberosities to your perineum and ischio-rectal fossa. But this is not the only source of pressure. Men, at any rate when they ride against a wind or up a hill, lean forward in order to present a less opposing surface to the wind or to throw their weight and centre of gravity directly over the pedals, and in this position of leaning forward bring much more pressure to bear upon their soft parts in front. To escape the former difficulty—i.e., the levering of the body forward by the act of pedalling—you may slightly tilt the peak of the saddle upwards, say 5° from the horizontal, and this will keep you fairly in your seat back upon the saddle, but it brings the peak up against the perineum, and when you lean forward you are worse off for apposition of the peak to the perineum than you were with the saddle in the horizonal. Many are the inventions which have been patented in view of this difficulty. A patent agent informed me a short time since that the patents handed in at the Patent Office for bicycle saddles only amount to fifty yearly, and a cycle accessory dealer wrote to me a few days ago saying that he has sixty or seventy saddles illustrated in his list for this season. But they may be divided for our purpose into two classes—saddles and seats; and I propose to go into this question, which appears to bear more upon cycling than surgery, because it is necessary that we should be able to advise our patients upon this subject, and to advise them well we must understand the subject thoroughly.

The first cycle was the hobby-horse, which might be described as a bone-shaker, without pedals, the feet being used as propellers on either side—punting on a bicycle. Obviously the position of the rider must have been hanging over a something which did duty for a saddle by his fork or perineum, and not sitting on his tuberosities. I should imagine that perineal pressure had a good deal to do with bringing this into disrepute. After a long hiatus which was partially occupied by the four-wheeled velocipede came the bone-shaker propelled by pedals on the axle of the front wheel where the saddle was retained, and as cycling has never since ceased the descent of the saddle may be thus briefly traced. Doubtless it was found to be more convenient than the seat of the velocipede, and in my opinion as a practical cyclist it undoubtedly is the best, and until something better and hitherto undiscovered arises the saddle or some modification thereof will remain. In spite of the advertisements of the makers of anatomical seats and the opinions of many eminent medical men I contend that for the work which has to be done on it the saddle-type of seat is the best, though I contend with an equal conviction that the ordinary make of saddle is bad and deleterious. I will take the seat first and will ask you to note that the absence of a peak, something to project between the thighs, means considerable loss to a cyclist. First, the peak keeps him on the saddle and steady, and without it he has to use some amount of force—very little it may be, but still some—to keep him on, and this is noticeable from the aching of the arms or thighs which attends the first efforts on a seat. Secondly, it deprives the cyclist of a considerable portion of one of his means of steering. These means are (1) the handle bar and (2) balance; and it is balance which is rendered easy by the peak of the saddle. I see letters in the cycling press from men who have become accustomed to seats who say that they find them more comfortable than saddles. I cannot claim to have given them a prolonged trial and so do not wish to pose as an authority on them; I have, however, tried those which I here show you and may give you my impressions of them.

1. The Burgess Seat is composed of two pads mounted on separate springs and capable of any adjustment necessary to make it fit the rider. So far as design goes it is ingenious, and one would have thought that the circular shape would have obviated the tendency of the thigh action to lever one off the seats, but I found the same difficulty in all the seats excepting La Sellette Papillon, that I had to use a definite amount of force both of arms and legs to keep on the seat, and any unusual jolt such as would pitch one forward in a saddle pitched one forward off the seat. I think that this seat is well suited to elderly riders who may have prostatic trouble and who do not want to ride fast and are careful in choosing their road. It has one advantage over the next which I

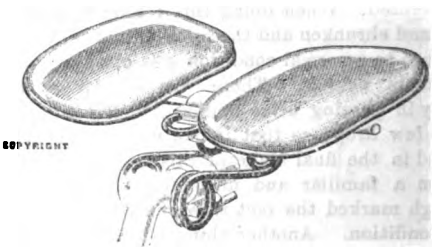
FIG. 1.



Burgess.

shall show you in having no resistance for the thighs to overcome in the act of extension. The seat or seats are made concave on their upper surfaces to take the ischial tuberosities, and I regard this seat as a good attempt at solving a difficult problem. 2. The next seat is the Autapto, which looks like two short thigh-splints distinct and parallel, and each one working on a well-adjusted recovery spring. It follows the thigh up from extension, but the resistance of the spring has to be overcome by the

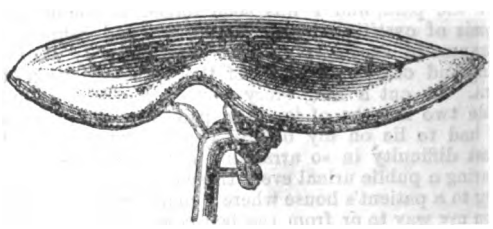
FIG. 2.



Autapto.

muscles which extend. I suppose that it would be arguable that the force thus expended in overcoming the resistance is restored as the spring brings the thigh up again, but this does not seem to me to be quite fair on the extensors, which certainly have the hardest part of the work to do. I found this seat less inclined to throw me forward than the others, as although I was always coming off on one side I was all right on the other. My impression of the Autapto is that it is comfortable and safe, though I must own to a distaste for the extra work which that recovery spring throws upon my hard-worked extensors. 3. La Sellette Papillon is, to my mind, the

FIG. 3.



La Sellette Papillon.

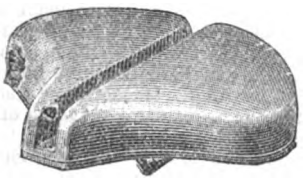
most comfortable of all, and I could be content to ride on it if I had to give up the saddle. It is a well-planned and comfortable seat, and the velveteen covering lends grip to the buttocks and so gives a feeling of security. In a short trial of it I found nothing to make me think it would cause saddle soreness, and I should place it first in the category of seats.

With regard to saddles it will be well for us to start upon this concluding portion of my paper with an idea as to what we want (1) to have and (2) to avoid. We want to have something that we can sit astride of (not hang over) and work our legs without hindrance or discomfort to our

Digitized by Google

thighs and without levering our tuberosities off the seat and on to the peak, and, further, it should provide means of escape for the soft perineal structures in case a jolt or voluntary alteration of position should tend to put pressure upon them. We want to avoid perineal pressure and anything which tends to riding forward off the broad part or to galling the buttocks or thighs. To meet these requirements I think it will be apparent to you that the surface of the saddle should be a plane and the saddle must be capable of a slight tilt backwards if the rider require such to keep him seated, and, secondly, a groove or opening for the perineum is advisable, though not essential, for in the Brooks' B 90 saddle you will find as comfortable a saddle as you can wish for. Then saddles may be divided into suspension and treed saddles, and for ease and comfort the suspension have my preference. The Sans Bec is misnamed, as it has a beak.

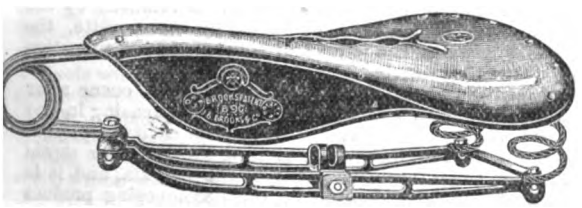
FIG. 4.



Sans Bec.

The peak is, it is true, reduced to a minimum and the sweep for the thighs is good. You will see that it is made on a tree which is perforated for the reception of symmetrical and ingeniously contrived rubber pads, which are placed on either side of a deep but too narrow central furrow. I expected to be comfortable on this saddle, but was not, and I think that the reason was that it was not roomy enough. I should get sore on it. It is a saddle which may be recommended to young men who care more for lightness and speed in riding than for actual comfort, and they need have no apprehension of perineal pressure. Suspension saddles are the various makes which are usually supplied and are usually faulty. There is, however, one which I mentioned just now, the Brooks' B 90,

FIG. 5.



Brooks' B 90.

which is comfortable, and from its length practically safe. Furnished with an elastic, easy, spring, it is most comfortable to ride upon though it will never come into general use, I fear, on account of its size and weight; but to those riders who do not heed these matters it will be found a desirable seat and may be slightly tilted backwards with advantage.

I have worked at this saddle question for some time and have had various wooden ones carved, each with an opening for the perineum, and I have found them not uncomfortable to ride upon. I have, however, a liking for the suspension saddle and have had these two made by a smith and

FIG. 6.

harness maker for my own use. You see that they are long and have an almost absolutely flat surface save only for the slight downward curve of the cantle. The peak has hardly any superior surface, being occupied almost entirely by an opening which runs back from the pommel and is preserved in one case by a metal fork and in the other by a wire. The peak, too, rotates round its horizontal axis and so provides a slight and comfortable amount of play with the thigh action.

This paper will be incomplete to a far more serious extent than it is if I omit all mention of women's saddles. I have had no case of injury to treat, but have been asked about chafing and soreness. As these occurred, without exception, in beginners one must not regard them too seriously. I think, however, that women are less liable than men to damage from pressure. They have not the exposed urethra, and have no prostate to be bumped about. Still they, or those who ride in skirts, have to use a short-peaked saddle, and I think that they would be as much benefited by a groove as men are. They do not ride as fast or as carelessly as men do, and so can somehow do better with a seat than we do. A word of practical advice to any who know of women who are beginning and have a fancy for the seat is that they ride on it as soon as they have learnt to keep on their machine, as the more they get accustomed to the saddle the more difficult they will find it to make the change. In conclusion, let me say that I can recommend no saddle as being universally applicable. I might as well recommend one pair of boots to fit everybody. Each rider has his peculiar method of sitting and pedalling, and each must select for himself a saddle which suits him. I do advise riders to try their saddles before they buy them, and to try them on a ride and not as they do a machine by a few turns up and down the street outside the agent's shop. They should understand thoroughly the right position of the saddle, which is such that they can, at the fullest extension required of the leg, sit properly upon the broad part of the saddle; and to obtain this the saddle must be low enough and far enough back, and probably in riding this position will be assisted by a slight raising of the peak. If the saddle is too high they are obliged to hang over the peak to reach the pedals, and if it is too far forward the leverage of the thighs throws them on to the peak and pommel. A good rule as to the height of the saddle is to see that at the point of greatest extension of the leg the heel can be brought to, or slightly below, the level of the pedal. Given a good saddle properly placed I am confident that only a few elderly riders need fear perineal pressure in cycling.

Exeter.

HÆMORRHAGE DURING THE EARLY MONTHS OF PREGNANCY.[1]

BY AMAND ROUTH, M.D., B.S., M.R.C.P. LOND.,

OBSTETRIC PHYSICIAN WITH CARE OF OUT-PATIENTS AT CHARING-CROSS HOSPITAL, PHYSICIAN TO THE SAMARITAN FREE HOSPITAL FOR WOMEN, ETC.

WHEN I was asked to read a paper at the South-West London Medical Society I thought over the various common obstetric and gynæcological ailments which most concern us as practitioners. In the special departments of medicine, obstetrics and gynæcology, the two symptoms which at once attract a woman's attention are *pain* and *hæmorrhage*. As an isolated symptom in gynæcological cases, pain is more likely to lead a patient to her physician than hæmorrhage. It is this fact which acts so disastrously during the course of uterine cancer, most patients neglecting the early hæmorrhage and discharge, only seeking advice when pain is superadded. In obstetric cases, on the other hand, where a woman believes herself to be pregnant, the onset of hæmorrhage usually induces her to send for professional assistance. I therefore chose Hæmorrhage during the Early Months of Pregnancy as the subject for my paper, and did so with the hope of learning a good deal more from my audience than I can hope to personally impart. I do not propose to discuss the subjects of accidental hæmorrhage or that arising from placenta prævia, for these varieties are best recognised in the later months and are for all practical purposes indistinguishable from other cases of threatened abortion, even if they should cause hæmorrhage in the early months. Cases of hæmorrhage during the early months seem to naturally fall into two groups: (1) where the hæmorrhage is

[1] A paper read before the South-West London Medical Society on May 13th, 1896.

Digitized by Google

directly due to the existence of the pregnancy, and (2) where it is due to some condition independent of, but concurrent with, the existing pregnancy. The following may be taken as a rough summary of cases coming under the two classes: (1) threatened abortion, missed abortion, incomplete abortion, moles (apoplectic ovum, carneous mole, hydatidiform degeneration of chorion), decidual endometritis (diffuse, polypoidal, and catarrhal), and extra-uterine gestation; and (2) persisting menstruation, granular erosion of the cervix, adenoma of the cervix, mucous polypus of the cervix, fibroids, malignant disease, and ulcerations (specific and non-specific). As a rule, we should be on our guard against the patient being pregnant in all cases of hæmorrhage between puberty and the menopause. Undoubtedly many mistakes are made from forgetting that a pregnant woman need not necessarily have amenorrhœa. It is very possible for a woman to be pregnant several months and yet to be either regular, or approximately so, or else to have metrorrhagia. So much is this the case that it would be safer to go to the opposite extreme and if a married woman complains of metrorrhagia—irregular hæmorrhages every day or every few days—assume for the time being that she is pregnant until this can be excluded. This mental reservation is often advisable in cases of unmarried women before the menopause, for it must be remembered that they may have special reasons for deceiving us as regards their menstrual history. I will now consider shortly the varieties named above in the first group.

Threatened abortion.—Here hæmorrhage is usually the first symptom, but if the abortion is becoming inevitable pain soon supervenes, the cervix dilates, the ovum begins to protrude, and perhaps the membranes rupture. If protrusion has commenced partial separation must have taken place, and the abortion should be encouraged. Short of actual protrusion, where hæmorrhage is not severe, attempts may be made to prevent the abortion. I need not here speak of this. If the abortion be deemed inevitable a warm antiseptic douche should be given, and if hæmorrhage be slight, and especially if the pregnancy be under twelve weeks in duration, the case should be left to nature. If hæmorrhage be profuse plug the cervix and vagina with gauze and give ergot, or else, as I personally much prefer, put the patient under anæsthesia, dilate up the cervix by the rapid method if the cervix will not yield to the finger, and gently strip off the entire ovum from the uterine wall, if possible without rupturing the sac, using the finger as a sensitive curette, meanwhile keeping the uterus firmly pressed down on to the inside fingers by means of the other hand. After removal of the ovum, douche out the uterine cavity with iodised water, and if hæmorrhage be profuse plug the uterus with antiseptic gauze—a means which I have never known to fail.

Missed abortion.—These cases are not always easy to recognise. A woman misses a period or two, followed maybe by a rather sharp loss, and may then begin to lose a little every day or once a week, or even have gushes of blood approximately every month, and, excusably enough, has no idea that her uterus contains an ovum. In some cases the ovum thus retained is changed, by extravasation of blood into its tissues, so that it becomes an apoplectic ovum, and as such will be considered later. The diagnosis of a retained dead ovum is made chiefly by the fact that one or two periods have been missed, by the presence of irregular hæmorrhages, and by the fact that the uterus is smaller than it should be, dating from the last regular period, and that, moreover, it is not enlarging, but tending rather to decrease in size. It has to be distinguished from subinvolution of the uterus after an early abortion, from incomplete abortion, or from molar pregnancy, and it may at first be impossible to be sure; but fortunately in all these cases ergot may be given, and its influence upon the uterus under these several conditions will go far to enable a diagnosis to be made. If, however, hæmorrhage persist, or the temperature rise, rapid dilatation should be effected under anæsthesia, the cavity explored, a complete diagnosis thus made, and the condition found at once dealt with. Cases of missed abortion, apart from those which result in the formation of moles, most usually occur when the ovum dies, as it were, very slowly, a lingering death from some lack of vitality either in the impregnating spermatozoon, as in cases of syphilis, Bright's disease, diabetes, or lead poisoning in the husband, or from similar or other chronic blood states such as anæmia in the woman. In such cases the uterus becomes tolerant to the presence of the degenerating and eventually dead ovum and may not at once throw it off. In such cases, also, the uterus would be less vascular and consequently less active. On the other hand, when the ovum dies more suddenly, an immediate abortion follows, except where extravasation of blood or decidual endometritis has made the membranes unduly adherent. Sudden death of the ovum is due to high temperature or to blood poisoning, as in acute specific fevers or in cholera &c., or to imperfect aeration of blood in cases of pneumonia &c. The following case shows how serious even a short retention may become.

CASE 1.—A married woman, seen with Mr. Busfield of Clapham, had had two children, the last eight years previously. She had been quite regular, her last period having been fourteen days ago. On April 3rd she began to lose a little blood, and this continued slightly for three days, and during the same period her temperature rose and rigors occurred. Though the history was very misleading Mr. Busfield suspected a missed abortion, and on the fifth day I saw the patient with him. She had then just had a rigor and her temperature was 106° F. Occasional uterine colic was present, but no other discomfort. Under anæsthesia an intact six weeks' ovum was removed, and in one and a half hours her temperature was 103°, in three hours 99·5°, and it was normal next morning. Hæmorrhage was rather free after removal of the ovum, requiring plugging of the uterine cavity with gauze.

The following case had less severe symptoms, but was remarkable from the ovum having died within a few days of reaching the uterine cavity.

CASE 2.—A married woman aged twenty-eight years, who had had one child seven years previously, aborted in March, 1895. She was quite regular till her September period, 1895, when she lost rather profusely, and continued to lose almost daily for the following five weeks, when, finding that the uterus was only slightly enlarged, to be not increasing in size, and that the hæmorrhage was getting worse, I rapidly dilated and found an ovum of about ten days loosely attached to the left cornu. She lost rather freely for ten days, but has since been quite regular. This very early ovum had apparently been conceived about ten days before the September period, had not been thrown off when that period occurred, and had been retained for another six weeks.

CASE 3.—A fœtus [which Dr. Routh showed] had been retained *in utero* for five months, causing metrorrhagia and septicæmia. Finally the uterus was rapidly dilated by Dr. Gibson Berkeley of Camberwell, the fœtus removed by the finger and the sloughing membranes by the curette, the woman doing well. The fœtus had undergone mummification and partial calcification.

Incomplete abortion.—If hæmorrhage or sepsis occur after a presumed abortion and the uterus is not increasing in size the cervix should be rapidly dilated and its cavity explored. True septicæmia in such cases is rare, sapræmia or septic intoxication being the usual cause of the pyrexia, and it is as a rule found that removal of the decomposing product causes the temperature at once to drop and the hæmorrhage to cease. The technique of the operation is as follows. The essentials are (*a*) rigid antisepsis, (*b*) dilatation so as to admit the finger, (*c*) complete evacuation of the uterine contents, and (*d*) anæsthesia is almost an essential. After washing the vulva and vagina with wool soaked in corrosive sublimate solution, seize the anterior lip of the cervix with a vulsellum forceps with blunt teeth like Teale's forceps. If the finger cannot be inserted dilate rapidly with graduated bougies and explore the whole cavity very carefully, especially the cornua, pressing the uterus down from outside. Remove any pieces found adherent with the finger if possible, or with the forceps or blunt curette as may be most convenient, but be careful not to injure the uterus, the tissues of which are very soft after abortion. For hæmorrhage apart from sepsis the curette is hardly ever required and in very rare cases should the curette be a sharp-edged one. If the piece removed be offensive the uterus should be irrigated with 1 in 2000 corrosive sublimate solution. If, as often happens when a piece of placenta is removed, very free hæmorrhage occur, the uterus should be at once plugged with iodoform gauze, a process which in my experience has in these cases never failed to arrest the bleeding. The gauze should be removed in twenty-four hours. Most cases of incomplete abortion are easy to diagnose, owing to the history of amenorrhœa, followed by hæmorrhage, passage of the fœtus, and subsequently more or less continuous losses. Where these points are denied the diagnosis is impossible without an exploratory dilatation, as in the following case.

Digitized by Google

CASE 4.—A woman who had been married three years had borne one child two years ago and had never aborted. Her present illness began with rather profuse hæmorrhage six months before, commencing fourteen days after a natural period. Since then she had lost blood daily, with no increase by which a menstrual date could be fixed, though she had had several severe floodings at irregular intervals. She came under the care of Dr. Murphy of Twickenham six months after the first hæmorrhage, and with his assistance I explored the uterus and removed a piece of placenta which had undergone some fibroid change, and had presumably been there for at least six months, though her view of it was that it had been there since her previous labour two years before. If so, it had produced no symptoms for the first eighteen months—a very unlikely alternative.

The following case is one of a rare condition where the placenta and membranes had come away and the fœtus had been retained. It was most probably a case of placenta prævia where the placenta from some accidental cause had become prematurely detached.

CASE 5.—A married woman aged twenty-six years had had three children, the last eleven months previously; two abortions had occurred prior to the birth of the last child. Amenorrhœa occurred from March 1st to May 3rd. She then "flooded" and had severe pain and passed several "pieces of flesh." Since then (six weeks) she had lost blood daily with occasional fœtor. She suffered much from backache, general malaise, and nausea. On examination the uterus was found to be bulky, flabby, and four and a half inches long, and I believed it was a case of abortion with probably a retained piece of placenta and put her on ergot till arrangements could be made for dilatation. In two or three days she had a series of sharp pains and passed a somewhat shrivelled, macerated fœtus of about three months' gestation with no clots, and digital exploration of the uterus proved that the afterbirth had also come away, probably over three months previously.

Molar pregnancy.—The "moles" most ordinarily met with are "blood moles" or "apoplectic ova," which are due to hæmorrhages into the decidua or between the decidual layers. Less frequently "fleshy moles" are found, due generally to hæmorrhages which have become organised or which are complicated with a good deal of diffuse or polypoidal decidual endometritis. These moles may remain *in utero* for many months, usually acting as foreign bodies and keeping up daily or irregular hæmorrhages. Sometimes the uterus becomes tolerant to their presence and menstruation may for a few periods become regular, but sooner or later the mole will be expelled with smart hæmorrhage and some pain, which latter symptom may, however, be almost entirely absent. Apoplectic ova are probably instances of the commonest pathological changes of the early ovum.

CASE 6.—[Dr. Routh showed a specimen of an apoplectic ovum which was expelled seven months after conception.] The woman had not been "unwell" for five weeks, when some hæmorrhage occurred, and doubtless at the same time hæmorrhage also occurred into the envelopes of the ovum itself, leading to the death of the fœtus. At first I diagnosed missed abortion and put her on ergot. All irregular losses then ceased and she menstruated regularly and I thought I had been mistaken, but at the seventh month the ovum was expelled with some hæmorrhage and practically no pain.

CASE 7.—In June, 1891, I saw a patient with Dr. Dodson of Wandsworth with a history of having had no regular period for six months, but she had had for over four months a daily grumous discharge, which for the last four weeks had gradually given place to offensive watery discharge. On examination the uterus was found equal to the size of a three months' pregnancy, and we came to the conclusion that the fœtus had died in the second or third month and was now retained, and had undergone some organic change and was probably a fleshy mole. As, however, the diagnosis was uncertain we gave her ergot on trial, and the hæmorrhages ceased, but in September—i.e., ten months after conception—the mole came away spontaneously.

Hydatidiform degeneration of the chorion—"*hydatid mole.*"—This can only be diagnosed with certainty by the discovery of cystic villi in the discharges, which are mainly watery blood, but it may be strongly suspected if the uterus is a good deal larger than it should be at the date to which we believe the pregnancy is advanced. This is just the opposite to what occurs with apoplectic ova or fleshy moles, where, though we gather that the woman should be three or four months pregnant, we find the uterus about the size of six or eight weeks. These hydatid moles may also remain *in utero* many months. If hæmorrhage be severe the uterus should be emptied, trying to do this with ergot first, and, failing that, by rapid dilatation. If hæmorrhage is slight, and yet the diagnosis is sure owing to vesicles having been detected, we should not be too much in haste to empty the uterus, as twin pregnancy may be present, only one of which is hydatid.

CASE 8.—[Dr. Routh showed a specimen of hydatid mole from a patient who was sent to him by Mr. Stanley Boyd.] She had had constant daily hæmorrhage for two months after two and a half months' amenorrhœa. The uterus was the size of a six months' pregnancy. Rest in bed made no difference, and as the discharge became offensive and the temperature rose full doses of ergot were given and this mole came away, some fragments in addition having to be digitally removed subsequently. Two years later she had a healthy child.

Decidual endometritis.—Next to apoplectic ova the commonest pathological change in the early ovum is decidual endometritis—diffuse, polypoidal, and catarrhal. Of these the catarrhal form is the most frequent, especially in women who have previously had subinvolution and chronic endometritis. Not infrequently one is able to trace a syphilitic taint, which in a few cases has been congenital. In such cases women may lose a little blood-stained or brownish discharge and as a rule do not believe themselves to be pregnant. After a few weeks the discharge may become watery and gushes of clear or straw-coloured water come away, being one form of hydrorrhœa gravidarum. These cases give rise to more mistakes in diagnosis than either moles or the other varieties of abortion already considered, but if a careful bimanual examination be made the diagnosis is not difficult. The uterus is found to be about the size we should expect in a normal pregnancy of the same duration, not larger, as in hydatid mole, and not smaller, as in cases of missed abortion or fleshy mole. The examination is made the more difficult because, owing to the unhealthy state of the uterus, its upper limit cannot always be felt and its intermittent contractions are very transient. If ergot be given incautiously or the uterus be roughly handled the uterus, already holding its contents very loosely, expels the ovum. These cases have also to be distinguished from both subinvolution and fibroids. Most of these cases go on to full term if treated by three or four grains of iodide of potassium thrice daily. This drug seems to be almost a specific remedy, though it is impossible that all cases can be syphilitic. The most typical cases of decidual endometritis occur in small-pox, and, owing to the hæmorrhage, have been called "hæmorrhagic endometritis," but these are exceptional in usually ending in abortion. The following case occurred after the menopause had apparently set in, rendering the diagnosis somewhat obscure.

CASE 9.—A patient aged forty-five who had been married twenty years had had eleven children, the last three years previously. Menstruation was regular till March, 1891, then amenorrhœa supervened till August, 1892, when she "flooded," and had in January, 1893, for over five months lost blood almost daily. Pregnancy of five and a half months was diagnosed, and she was put on iodide of potassium to cure the endometritis. The hæmorrhage soon ceased, occasional gushes of clear water passing painlessly. She was confined on April 15th of a healthy child, but the placenta being pathologically adherent from the endometritis had to be stripped off.

Extra-uterine pregnancy (mainly tubal).—This cause of hæmorrhage must not be omitted, though relatively rare. One or two periods are missed, sometimes only one; then irregular hæmorrhages occur, and possibly a uterine decidua, differing from that of an intra-uterine pregnancy in having no chorionic villi, is passed. Physical examination reveals a sympathetically enlarged uterus and a tumour on one or other side or in Douglas's pouch. Possibly also the patient may complain of pain—the pain of tension—on that side also. The treatment is to remove the tube as soon as the diagnosis is sure. If rupture has already occurred downwards into the broad ligament nothing operative need be done, as the hæmorrhage is necessarily bound down. If rupture has taken place into the peritoneal cavity, and it can be felt to be encysted by pre-existing bowel adhesions which roof over the pouch of Douglas, we may delay operation hoping for permanent arrest of bleeding; but if no *localised* hæmatocele be felt an internal hæmorrhage is evidently going

Digitized by Google

on, the abdomen must be opened at once, and the ruptured tube removed.

The second large group of hæmorrhages during the early months of pregnancy consist of those varieties due to conditions concurrent with and complicating the pregnancy.

Persisting menstruation is fairly common during one, two, or three months, and in the last case the uterus would be found to correspond in size to a gestation of three months longer duration than was indicated by the amenorrhœa. Physical examination would distinguish these cases from hydramnios, and the absence of irregular losses would prove them not to be hydatid moles. The most likely mistake to fall into is that the large uterine tumour may at the end of the three months' pregnancy be taken for a fibroid tumour. Time, however, will always clear up the case.

I will now very briefly consider some of the local complications which cause hæmorrhage during early pregnancy.

Granular erosion of the cervix.—Here the hæmorrhage is slight and as a rule only present after coitus.

Adenoma of the cervix.—If a granular erosion has been present before conception there will have been a denudation of the squamous epithelium of the vaginal portion. The coexisting glandular cervicitis is aggravated by the increased vascularity of pregnancy, and the resulting projections of papillary processes look like the tentacles of a blood-red sea-anemone. Such a cervix bleeds freely when touched, and when not touched there is usually a blood-stained leucorrhœa. This condition disappears spontaneously after delivery, and can be held in check during pregnancy by usual local remedies.

CASE 10.—A married woman aged thirty years had had one child four years ago. She aborted eighteen months ago. She had had severe endo-cervicitis and erosion. She had now had amenorrhœa for two months, except that she always lost blood after coitus and had a copious leucorrhœa, occasionally blood-stained. The uterus was found to be retroverted and gravid. The cervix was bright red, bled easily on contact, and was evidently adenomatous. The uterus was reduced and the cervix painted a few times with iodised phenol. She went to full term and did well.

Mucous polypus of the cervix.—A woman may perhaps be suffering from almost daily loss of blood, yet becomes pregnant and continues to lose blood as before. The uterus is found to be enlarged, and, naturally enough, if great care be not taken the diagnosis of rapidly growing fibroid is made, and the mucous polypus, even if noticed, is then looked upon as an unimportant complication.

CASE 11.—A woman aged forty-one years had been married four months. She had slight irregular losses before marriage and more severe and frequent since. She was thought to have a rapidly growing fibroid requiring operation. She was found to be about three and a half months pregnant and had two small mucous polypi hanging from the endocervix. These were burnt off and her child was born in due course.

Malignant disease of the cervix.—I do not know of any case of pregnancy occurring where pre-existing cancer or sarcoma of the body of the uterus was present, but it is possible that some of the cases of deciduoma malignum recently reported may be thus explained. Cancer of the cervix and pregnancy are not nearly so rare, and it is evident that with such a cause of hæmorrhage existing, a mistake in diagnosis may be easily made.

CASE 12.—A woman came to the out-patient department of Charing-cross Hospital suffering from metrorrhagia of some months' duration. This was found to be due to epithelioma of the cervix, already beginning to slough and ulcerate. She had a large uterus, but the question of pregnancy did not occur to me. She was admitted and I removed the cervix as high as the internal os uteri, and even then had no suspicion that she was over two months' pregnant. She disappeared from under observation, but I subsequently heard that she went to full term, that the epithelioma speedily recurred, as it always tends to do during pregnancy, and that during a temporary closure of the hospital she went to St. Thomas's Hospital, and Dr. Cullingworth successfully performed Cæsarean section, the woman dying some months after from the malignant disease.

These few cases and my imperfect comments will tend, I hope, to show how important a careful and cautious diagnosis is in all instances of metrorrhagia where pregnancy is a possible explanation or concurrency.

Manchester-square, W.

THE TOXINE THEORY OF SYPHILIS.

BY ARTHUR H. WARD, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, LONDON LOCK HOSPITAL; SURGICAL REGISTRAR TO ST. GEORGE'S HOSPITAL.

IN a paper on the Pathology of Syphilis[1] I advanced a working hypothesis deduced from a consideration of the phenomena of the hereditary disease, and I have recently applied it to the question of latency in syphilis.[2] In order to cover the vast array of facts involved it is evident that such a hypothesis must be of elemental simplicity. Reduced to its lowest terms it may be stated thus: (1) syphilis is associated with the growth of a microbe in the organism; and (2) this microbe produces a toxine which is the active cause of the phenomena of syphilis. In the light of modern bacteriology this theory seems almost self-evident; however, until the specific microbe has been discovered, cultivated, and inoculated, and the toxine isolated, it must remain a hypothesis only. I will endeavour to show that, at any rate, it is one that will work. The toxine must be supposed to share the properties of other microbial toxines; for instance, it is diffusible and follows the laws of osmosis, it is irritating to the tissues and causes local inflammatory reaction, it is strongly chemotaxic and attracts leucocytes into the area in which it is present, and when existing in quantity in the circulation it causes symptoms of general toxæmia.

The first thing to consider is the point of original infection, the abrasion or fissure through which inoculation takes place. This is often so minute as to escape notice, and when more extensive—for instance, a torn frænum—the mere fact of its occurrence will put a stop to further exposure to the infection. It is, therefore, plain that only a few microbes can be implanted in the first instance, while the prolonged course of the disease indicates that the infection is a slowly developing one. Hence, although there is no reason why the primary colony should not start growing and forming toxine at once, yet it will be so small, or so sparsely sown with microbes, that the toxine produced will be inappreciable in amount. Chemotaxis will occur from the first, but three weeks may well elapse before sufficient toxine has been developed to cause a cell infiltration dense enough to distend the intercellular spaces and be visible to the naked eye. Thus the primary incubation period is one of apparent latency. When the spaces in which the colony is growing have become sufficiently crowded up with leucocytes the indurated papule, the first sign of syphilis, will result. The induration is the essential feature of the lesion, since ulceration is not invariable; this, however, almost always occurs. I believe it to be due to the degeneration of the invading cells from overcrowding and consequent mal-nutrition for the following reasons. Microscopical examination shows that the walls of the vessels are thickened and their calibre reduced by the presence of round cells—cells, I believe, in the act of invading the colony in response to the stimulus of the toxine; therefore, the blood-supply of the infected area is defective. Further, the surface of the early hard sore presents a whitish colour and is covered with a number of small, irregular depressions; it looks worm-eaten—"vermoulu," as Ibsen has it; these depressions can only be due to the disintegration of collections of cells massed among the fibres of the cutis. Again, when the primary induration consists of several confluent papules, ulceration occurs at several points corresponding to the centres of the several colonies, where the induration would be densest and degeneration most likely to occur; these ulcers ultimately fuse into one large sore. Lastly, when the primary sore is situated on a vascular part, like the lip, very little ulceration generally occurs, although induration may be most extensive. The worm-eaten appearance disappears in a few days and the sore becomes smooth and callous, because, I think, it must form a nidus for saprophytic microbes, whose toxic products will dissolve the superficial layers of tissue, as in other chronic ulcers. When the sore is beneath the prepuce, and the discharge retained, evidence of the presence of such toxic irritants occurs in the shape of acute irritation, suppuration, and possibly phagedæna. In the normal hard sore no suppuration exists because it is formed by disintegration only, as I have tried to show.

Since the primary colony is single, and there is no other

[1] THE LANCET, Sept. 10th, 1892. [2] THE LANCET, Feb. 22nd, 1896.

Digitized by Google

source of toxine, this body will diffuse into the blood with absolute freedom; consequently at the margin of the colony it will be instantly washed away and its chemotaxic influence will cease; therefore, the resulting induration will also cease, and thus the characteristic sharply margined induration of the primary sore is accounted for. It is evident that the position of this lesion is unique; never again in the course of the disease can the combination of a single colony together with a total absence of acquired toleration in the leucocytes occur; I think, however, that the solitary gumma occurring years later may occupy an analogous position, and here a similarly dense infiltration is found. As the primary colony grows peripherally into the tissues the induration will accompany it with equal steps, and the consequent ulceration follow after; in this way the sore increases in size. The actual size of a hard chancre will depend, firstly, on the area originally infected, a group of papules fusing into a larger sore than a single one produces, and a larger abrasion—a torn frænum, for instance—resulting in a lesion at first corresponding in outline to the tear and later tending to a circular form; and, secondly, on the rate of growth of the microbes into the tissues. This, again, depends on the resisting power of the individual; a rapid growth indicates weak resistance and a corresponding luxuriance of the secondary foci may be expected; so for prognosis the rate of increase, not the size of the lesion, is of importance.

The microbes in their growth in the primary colony will soon reach the beginnings of the lymphatics, and be carried in the lymph stream to the nearest gland, and thence to the whole group; some falling by the wayside will grow on the walls of the lymphatics, as is shown by the resulting induration; the rest will reach the first gland and grow in it, producing toxine and consequent infiltration and indolent enlargement. Thence the infection will spread to the other glands with a like result. The microbes are certainly present in the glands, since I have seen a hard sore under the nail follow the scraping out of such glands which had suppurated, presumably from a further infection by pyogenic microbes. If the infection can spread from gland to gland it can spread further and in this way reach the circulation. Thus microbes must be continually shed off from the primary glands and be carried by the lymph stream to the blood stream and so be scattered broadcast through the organism. They will ultimately be stranded on the capillary walls, probably at the most distant points of the periphery, such as the looped terminal vessels of the skin and mucous membranes, just the situations where evidence of their presence first occurs. It seems unlikely that more than one microbe would strand at a given point, hence I conclude that the secondary colonies generally start from a single microbe which multiplies indefinitely. The colony will grow through the vessel wall into the surrounding spaces, even penetrating the epidermis, as the contagious secretion of condylomata shows. These secondary colonies will again form toxine, which will diffuse into the circulation. So long as this process can continue no local irritation will arise and the colony will remain apparently latent. This apparent latency, as I have already pointed out, may continue in an infected fœtum for nine months, while the child is born apparently healthy, the explanation being that the toxine diffuses into the maternal circulation. At birth, however, this safety valve is shut off, toxine begins to accumulate, the child falls off, becomes wasted and anæmic, and shortly an outburst of secondary lesions occurs. I believe that a similar accumulation of toxine precedes the evolution of secondaries in acquired syphilis; there is a similar train of general toxæmic symptoms, such as malaise, anæmia, rise of temperature, and loss of weight. When the toxine tension in the blood reaches a certain point further diffusion from the microbic foci will be impeded, the toxine will be retained in the foci and produce local irritation, hence the development of the rash. That the accumulation of a microbic toxine in the blood can cause general and local reaction is demonstrated in the tuberculin treatment of lupus. Here we know for certain that bacilli are growing locally and forming tuberculin, which must diffuse into the circulation, where its presence is known by the general reaction following the injection, which in a healthy person would not occur. By the injection then the general tuberculin tension must be raised, and since all other circumstances remain unchanged the general reaction must be due to this raising of the tension. Since the tubercles are extra-vascular this circulating tuberculin can reach them only by diffusion, and this will be prevented by the presence of the tuberculin already in the tubercles; this local tuberculin will similarly be prevented from diffusing into the blood stream, and so accumulate and be the actual cause of the local reaction. It has been proved by experiment that an injection of tuberculin in a case of secondary syphilis also causes general reaction, and in a case of rupia local irritation similar to that occurring in lupus. Therefore, the toxine of syphilis must be so similar to tuberculin that one body can impede the diffusion of the other. The secondary foci in syphilis differ only in number and size from rupial foci, and as units occupy a similar position to the organism as a whole; it cannot make any difference to them individually whether tension is raised and local diffusion impeded by an injection of tuberculin or by the production of toxine in countless other foci. I therefore conclude that the outburst of secondaries depends on the accumulation of toxine in the blood, and this accounts for the polymorphism of the rash, since all foci above a certain size will share the irritation and be revealed. The older and larger foci will naturally be the most irritated, since more toxine will be produced in them; hence the corresponding lesion will be larger and more active. The youngest colonies will, on the other hand, not produce enough toxine at first to show reaction, but as they grow irritation will develop, fresh lesions appear among the old ones, and as the latter die down the eruption will present lesions in every stage of development and decline. When the secondary outbreak is acute I have sometimes noticed a corresponding irritation in the primary sore which is diffusely indurated, hot, red, and inclined to discharge; indeed, when I see a primary sore in this state I confidently expect to find a marked display of secondaries. The primary sore ceases to grow at this stage, and presently cicatrises and disappears or becomes converted into a scaling patch or mucous plaque. This happens even when the secondaries are evolving. It seems to me that the cells invading both primary and secondary foci must attain after a time sufficient toleration to fall upon the microbes. The acquisition of this toleration may, I suppose, be connected with the formation of an antitoxin. Now, the cells in the primary focus have been exposed longer than those elsewhere, so it is natural that they should be the earliest to acquire toleration and be able to encapsule the microbes and destroy them more or less. Consequently the production of toxine will cease in the primary focus, and the cells, no longer being attracted, will tend to wander back into the blood. So the induration will melt away and the sore be able to heal.

A similar process will follow in the secondary foci in ordinary cases, the tolerant cells will encapsule the microbes and restrain their growth. Toxine formation will largely cease, the invading cells disperse, and the signs of irritation disappear. At the same time the toxine tide in the blood will fall and a period of apparent latency set in. The much less marked cell infiltration of the secondary lesions as compared with that of the primary sore is due, I suggest, to two factors: firstly, the general toleration which the leucocytes must acquire will render them less susceptible, and, secondly, the toxine tension in the foci will not be greatly higher than that in the blood, and its stimulating effect on the cells will thus be minimised. At the same time the toxine will diffuse with difficulty and tend to hang about the foci, hence the induration which exists will fade gradually into the normal skin and not be sharply margined. Although the secondary rash is polymorphic, yet in different individuals different classes of lesions obtain, in one scaling papules of different sizes, in another roseolous patches; one case I remember in which the primary lesion presented no ulceration, and the secondaries were simply macular without the least tangible infiltration, showing that in this individual resistance was such as to prevent infiltration enough to be followed by ulceration in the primary lesion, while in the secondaries it was even less marked. The foci growing in the mucous membranes follow a like course to those in the skin modified by local conditions. There is no reason, I think, why foci should not develop elsewhere, and periosteal pains may indicate their presence; however, since they are small at this stage evidence of their existence in deep situations cannot be expected except in the worst cases. The general enlargement of the lymphatic glands will, I think, be due to the same cause as the primary bubo—namely, the growth of microbes carried from the secondary foci to the corresponding glands. It is not necessary that these foci should ever have been large enough to be revealed, while, on the other hand, they may

Digitized by Google

well have died down before the glandular enlargement appears That this enlargement will persist long after the secondaries have so disappeared is quite likely when the structure of the glands is considered, for it is evident that after toleration has been acquired and the microbes encapsuled and destroyed the phagocytes will regain the circulation much more readily from the cutaneous lesions than from the recesses of the glands. The pigmentation of the secondary lesions must, I think, be due to the local action of the toxine on the red corpuscles, just as general anæmia results from its accumulation in the circulation.

(To be continued.)

THE REFLEX INFLUENCE OF ALVEOLAR LESIONS ON THE VOCAL CORDS.

BY W. R. TUCK, L.D.S. R.C.S. ENG.,
LATE HONORARY DENTAL SURGEON TO THE TRURO HOSPITAL.

ONE who has been engaged in the active pursuit of dental surgery for a considerable time can scarcely fail to have met with strange and mysterious cases which in diagnosis and treatment baffle the efforts of the most experienced and skilful practitioner. When commencing this article it was my intention to confine the subject to that of neuralgia in its almost endless and protean forms. A unique manifestation of diseased action lately brought under my notice has, however, decided me to deviate from my original intention; I have therefore to introduce my subject metaphorically in order that it may be more clearly understood by the readers of THE LANCET.

If we take the whole range of musical sounds as exemplified, for instance, in the violin, and find them all in point of tone and quality to harmonise, we then pronounce such an instrument to be of a perfect type and its commercial value almost fabulous. It is not unusual to hear of such a sum as £2000 being paid for an instrument of that description. I was at one time intimately acquainted with a gentleman who had made the theory of music a profound study for many years. Moreover, he was an advanced mathematician and probably made millions of figures in his geometrical calculations of proportion in the different parts making up the entirety of the instrument. His knowledge of acoustics was also considerable, and as the financial position of this gentleman was equal to the enlightenment of his mind he spared no expense in providing for experiments, in the hope of discovering the true and definite principle on which all instruments of this class could be accurately constructed according to the Amati or Stradivarius method. I was on one occasion invited to his house to see a violin he had recently purchased in London and for which he had paid £30. It must not be imagined that the instrument commanded that price for its excellence—just the reverse, for the dealer assured this devoted amateur that it had been used in the Italian opera orchestra for a considerable time, but had suddenly failed in its tone. This fact excited the curiosity of my friend and strengthened his desire to purchase it that he might avail himself of the opportunity to examine the make and shape in a critical manner in the endeavour to find the cause of failure. He commenced by first removing the cover, and on minute examination of that part it was found that a worm had eaten a small hole in the bass bar. This discovery was made known to the vendor and the violin returned with instructions for a renewal of the defective part. When that was done the instrument was restored to its original state and value. In all the intricacies and mysterious working of the human system diagnosis is at all times difficult and successful treatment no less so. I have lately met with a case in practice which seems so analogous to the one just described, although in two different natures, that a narration of it may not be uninteresting.

A clergyman in endeavouring to utter the letter *h* set up a spasmodic action of the vocal cord which took him a few seconds to recover from ere he could proceed with his discourse. This remarkable affection gave rise to much speculation among the members of his congregation as to the cause. Within the past few months an opportunity has been afforded me for an oral examination, and having noticed a great deflection in the right inferior maxilla where the first molar and second bicuspid were formerly situated I interrogated him as to the cause. He informed me that these teeth had been extracted by a non-qualified man, who had removed a large portion of the jaw with them; so much so, indeed, as to injure both the nerve and artery—in the first instance interfering seriously with the neurotic force and in the second disturbing the arterial current. It instantly occurred to my mind that this terrible mischief was the cause of his lamentable malady produced by reflex action on the particular cord; there can be little doubt that the damaged part described had originated the affliction from which he suffered and with little chance of amelioration. Here we have evidence of a bungling mutilation by a non-competent operator, with the unhappy result of destroying the best prospects of a useful life.

Truro.

A RECORD OF THE DEATHS OCCURRING AMONGST 400 ADOLESCENTS BETWEEN JAN. 1ST, 1871, AND DEC. 31ST, 1895.

BY CLEMENT DUKES, M.D., B.S. LOND.,
PHYSICIAN TO RUGBY SCHOOL AND SENIOR PHYSICIAN TO RUGBY HOSPITAL.

IN continuation of my three papers which appeared in THE LANCET of Feb. 15th, March 28th, and May 2nd, 1896, I am able, by the courtesy of the present head-master of Rugby, who is very keen on all questions relating to the health of the school, to place before the profession an account of our mortality during the twenty-five years commencing Jan. 1st, 1871, and terminating Dec. 31st, 1895. During this period the average number of boarders has been 403. The ages range between thirteen and nineteen years. There are eight months spent at school and four months passed at home each year. The deaths during term, therefore, ought to be at least twice the number of those occurring during the vacation, while if allowance be made for the aggregation of so many young people the proportion should be still greater.

1.—DEATHS ARISING DURING TERM.

1. *Pneumonia*.—A case occurred in March, 1875, and death took place between the fifth and seventh days, as usual, from failure of the heart's action.

2. *Pleurisy*.—A case appeared in June, 1877, and death took place at the end of the fifth week suddenly from syncope owing to pleuritic effusion. In those days it was a disputed point as to the value of early tapping. Had this case arisen a year or two later paracentesis would have taken place early before tension occurred and probably a life have been saved.

3. *Scarlet fever*.—A case occurred in March, 1881, and although it was a mild type of fever death took place on the fifth day. I believe that the mother and four children in the same family had previously died from scarlet fever.

4. *Diphtheria*.—A case arose in July, 1883, and death took place from exhaustion. The lad was a great naturalist, and had been searching for some of his treasures in the black mud of a ditch, of which his nails were full.

5. *Typhoid fever*.—This case occurred in December, 1889, and death arose from perforation on the twenty-fourth day. It originated from eating oysters which were sent as a present from home, and which had come from the mouth of the Liffey or of the Mersey.

6. *Cerebro-spinal meningitis*. — This case occurred in November, 1893, at the very onset of an attack of influenza, and death took place on the third day.

7. *Death while running*.—This took place in November, 1892, during a run of about three miles, from disintegration of the blood. The runs are now so safeguarded and classified according to age and physique as to be within the compass of all healthy boys, who can but be benefited by participating in them.

8. *Peritonitis*.—This case occurred suddenly, after a day or two's illness, in July, 1894, and arose in all probability

Digitized by Google

from the rupture of a suppurating mesenteric gland; the patient had suffered from mesenteric disease some years previously.

II.—DEATHS ARISING DURING THE VACATION.

1. *Diphtheria.*—A case occurred while on a visit to the Isle of Wight in September, 1887.

2. *Scarlet fever.*—A case occurred in April, 1890, while studying French in Paris.

3. *Erysipelas of head and face.*—This case occurred in 1891 at home.

TABLE I.—*Showing the Diseases causing Death during Term and Vacation between Jan. 1st, 1871, and Dec. 31st, 1895.*

Diseases causing death.	During term.	During vacation.
Pneumonia	1	—
Pleurisy	1	—
Scarlet fever	1	1
Diphtheria	1	1
Typhoid fever	1	—
Cerebro-spinal meningitis	1	—
Erysipelas of head and face	—	1
While running	1	—
Peritonitis	1	—
Total number of deaths which occurred during term and vacation	8	3

TABLE II.—*The Mortality arising amongst 400 Adolescents during the Twenty-five Years commencing Jan. 1st, 1871, and terminating Dec. 31st, 1895.*

Deaths arising from all causes per annum.		Death-rate per cent. per annum.
Term = two-thirds of year	0·32	0·08
Vacation = one-third of year	0 12	0 03
Total for year =	0·44	0·11

In all the previous series of papers the records have related to the *boarders* at school only, as I have no knowledge of the *day scholars* except in so far as individual parents do me the honour to consult me. But in recording the deaths I could not feel it consistent with my duty under any pretext to omit a death in any part of the school, whether in term or vacation. The average number of boarders in the school has been 400, but when the day scholars are included the average is as nearly as possible 435. The two deaths, Nos. 7 and 8, occurred amongst day scholars, and although they were both under my care, yet in strict accuracy they should not be included in calculating the death-rate amongst 400, but amongst 435, which reduces it from 0·08 per cent. to 0·07 per cent. Further, this makes the deaths amongst the boarders at school exactly the same as amongst the boarders at home when the time is taken into consideration. Or, to put it in another form, during a period of twenty-five years, amongst 435 adolescents, 6 died while residing at school, and 5 while residing at home.

It will have been observed, in studying these records which I have had the honour and privilege of placing before the profession, that of recent years some of our *illnesses* have apparently increased, which should not be the case with our extended experience. But the increase is only apparent: it arises from an increase in *numbers* in the school; for whereas during the twenty-five years we have had an average of 435 all told, at the present moment there are 539 boys in the school.

What a privilege it will be for the physician who records the next twenty-five years of medical school work, for with early paracentesis for pleurisy, with certainly antitoxin for diphtheria and possibly antitoxins for pneumonia, scarlet fever, typhoid fever, cerebro-spinal meningitis, and erysipelas, he will scarcely require certificates of death to be placed at his disposal.

Rugby.

SOME REMARKS ON VAPOURS, SPRAYS, AND FUMES.

BY ROBERT LEE, M.D. CAMB., F.R.C.P. LOND.,
LATE PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C., ETC.

WHEN the great benefits which have been obtained from the inhalation of chloroform, ether, and nitrous oxide are observed it must be admitted that the administration of agents in the form of vapour is a subject of interest and importance. The change of any substance from the fluid state to that of vapour is generally due to the action of heat, and this is also true when the substance is changed from the solid state to that of vapour. When such substances as opium or the leaves of various plants are converted into the form of vapour it is usually necessary to effect the change by the process of combustion—that is, by raising the temperature far above that which is necessary when the substance we are treating is in the fluid state and requires only to be raised to its boiling point—at least, not above it. It is proper, therefore, to distinguish clearly between vapours, sprays, and fumes, for sprays are only changes from the fluid state to one of very fine division of particles, without elevation of temperature; while fumes are the results of slow combustion, which effects not merely a change of condition of material, but a disintegration of components and often some chemical decomposition.

How little this subject is understood is proved by the last Pharmacopœia into which the vapores were introduced. Any criticism of these "vapores" is unnecessary, as their inutility and insignificance are generally recognised. Whenever the physician desires to administer any medicinal agent in the form of vapour he finds it difficult to determine without further experiments how he may best effect it. If he takes that class to which camphor, menthol, benzoic acid, and many other species belong he will have to consider whether they require to be dissolved in water or some more active solvent in order that he may obtain them in such form and strength that allow of their inhalation. If he dissolves one of them in some liquid which he can easily convert into vapour, the question will have to be decided to what extent the substance he has dissolved is affected by the vaporisation of the solvent liquid. In some cases he will find that the active substance is volatilised much below the boiling point of the liquid and in others very little if at all so. Although an oil such as that of eucalyptus floats on the surface of water it is not easy to volatilise it by boiling the water, while such a substance as thymol is volatilised with a rapidity far greater than that of the water which contains it.

These general remarks are made simply for the purpose of directing attention to the need that exists for far greater knowledge than is possessed at present, not of the therapeutic value of various agents, but the mode in which they should be treated in order to have them in such a form that they can be used for clinical purposes.

In regard to sprays the physician is in a better position, as there are various well-arranged instruments which enable him to convert fluids into the form of sprays by the simple action of atmospheric pressure and admixture.

When the question of fumes is considered the strange and vastly wide influence exerted by the smoking of tobacco, opium, and a few other vegetable substances cannot but be attentively regarded. On analysing what is meant by the term "smoking" it is seen that really combustion is promoted by the effort of inspiration and that thus are converted into the form of vapour the active properties of the vegetable substances that are employed. One cannot obtain the active property of opium by volatilisation in such a form that it can be inhaled in the same way that a volatile substance like menthol or camphor can be treated. Opium may be added to water or spirit, but if the solution is heated the liquid does not part with the opium and no effect is obtained by its inhalation. To convert opium into the form of vapour slow combustion must be used, and how this may best be done requires consideration. The same remark applies to many other active medicinal agents—notably datura and stramonium and cannabis indica. I am not dealing with the question of the therapeutic value of any of the substances, but with the best method of combustion. A simple principle has been applied by which this can be easily effected. By

Digitized by Google

the action of a jet of air playing in a small tube the combustion of the leaves of plants or of such a substance as opium is promoted and vapour is given off which contains the active properties of the leaves or other parts of the plant which is being burnt. Under the name of the "Zephyron" Messrs. Maw, Son, and Thompson are introducing to the profession an apparatus which acts in the way described, and whether any benefits may be obtained from its use remains to be tested by clinical experiment. The chief value of the zephyron depends on the entire novelty in that a small elastic ball produces the jet of air by which combustion is effected, and there is no necessity to use the heat of a spirit lamp to obtain the force required. It may be well to observe that the inhalation of fumes obtained from smoking is not an easy matter, for these fumes are not as a rule inhaled into the lungs. There seems to be some advantage in administering certain medicinal agents by inhalation over that of introducing them into the system through the stomach by administering them in the solid or liquid form. It is unnecessary to criticise the great benefits obtained by the method of subcutaneous injection, and I will not venture to compare it with the inhalation of fumes beyond remarking that the latter is simpler and more easily effected. Those who have seen the zephyron are favourably impressed with its utility, as it enables the physician to administer fumes to those who are unable to smoke, and even for some who can do so it makes inhalation far easier. Where the leaves of plants are used, as in the preparation of powders or cigarettes for the relief of asthma, there does not seem to be much difficulty in obtaining their combustion by the addition of nitre. The saturation of paper with solutions containing the active properties of drugs has long been adopted in the manufacture of cigarettes, but the fumes given off by this method cannot well be inhaled as they are more or less irritating to the mucous membrane. There is one material which may be used instead of paper for treatment with solutions, and this is the fine wool obtained from peat. It is true that the leaves of many plants may be moistened with solutions, dried, and then burnt slowly. For example, if the leaves of stramonium are moistened with an aqueous extract or tincture of opium fumes are obtained containing the active properties both of stramonium and opium. The leaves of various species of mint yield fumes which can be inhaled without irritation, just as is the case with the pure leaves of tobacco.

In the Materia Medica of the Hindus[1] mention is made of "Dhumapâna or Inhalations." It is stated that "tapers or pastilles made of medicinal substances are set fire to and their fumes inhaled through a tube by the mouth or nose," and that "incenses or tapers composed of various medical substances are also burnt in rooms." It seems, indeed, that the inhalation of fumes is a method of treatment of ancient date, and it is reasonable to think that the practitioner might avail himself of it at the present time with all the assistance given by advance of knowledge. To enter into details, however, is not the intention of the above remarks, which can only be regarded as an introduction to the consideration of a subject of great therapeutic interest.

Gunterstone-road, W.

THE PRODROMAL ERUPTIONS OF SMALL-POX.

BY FRANK ROBINSON, M.D. VICT.,
RESIDENT MEDICAL OFFICER TO THE CITY HOSPITAL, PARK-HILL, LIVERPOOL.

As so much attention is directed to the subject of small-pox at the present moment, the following note on the rashes met with in the initial stages of the disease may prove of interest.

Initial rashes were present in 25 of 220 cases which passed through my hands in the Bradford Borough Small-pox Hospital in the winter of 1893–1894, forming about 11 per cent. of the total cases. These eruptions, which take the form of an erythema or of subcutaneous hæmorrhage, are said to appear on the day preceding or on the same day as the papules of the characteristic eruption. Though described as being of but short duration I found them still present as late as the sixth, seventh, and eighth days of illness, the erythematous form, curiously enough, proving the more persistent. In several cases both erythema and hæmorrhage were met with at the same time. The erythema resembled the eruptions of measles and scarlet fever and was present in 10 cases. The measly form was usually fairly copious in amount, the arms being the favourite site, less frequently the trunks and legs, while the face was but once the seat of the eruption. The scarlatinal variety was most frequently found on the abdomen. The most pronounced case presented two complete zones round the shoulder and pelvic girdles united down the flanks. These erythemata faded to a dull yellow after two or three days, and finally disappeared from the fourth to the ninth day of illness. Elevation of the eruption was never observed and thus a strong point of difference was presented from the eruption of measles and from certain toxic rashes characterised by infiltration into the skin. Any appreciable resemblance to erysipelas was not observed. Subcutaneous hæmorrhage occurred in 18 of the 25 cases, taking the form of numerous petechiæ confined to a comparatively small area of the skin and thus differing in distribution and form from the subcutaneous hæmorrhages of hæmorrhagic small-pox which are individually much more extensive and are generally distributed. The deep purple or black hue of the latter variety was never attained to. While the lower part of the abdomen and the inner aspect of the thighs were the areas most frequently selected hæmorrhage was also to be seen in various situations on the trunk and on the upper arms. It was never met with below the elbows or knees or on the face. The latest date at which petechiæ were still recognisable was the seventh day of illness, careful distinction being made between the initial hæmorrhage and that which may make its appearance later in the course of the illness. These initial rashes appeared to favour no particular age-period, being met with anywhere between the ages of seventeen and forty-eight years. A remarkable point was their relative incidence on the vaccinated and unvaccinated, 23 of the 25 cases having been primarily vaccinated. The proportion in percentage of the vaccinated to the unvaccinated among those showing these eruptions was thus 92 to 8. This was not due simply to the excess of primarily vaccinated cases in the hospital, for their proportion of the total cases was not more than 70 per cent. The occurrence in vaccinated cases being so notable it was natural to look for distinctly favourable results from the collective cases, and this expectation was fully justified. Apart from any consideration of this kind, however, where erythema was present there was a very distinct relation observed between the prodromal rash and the true eruption which materially influenced the progress of the case. The papular rash either did not develop at all on the erythematous areas or did so to a very scanty degree, and as these areas were usually extensive the cases were thus of a mild type. This relation was shown from the opposite point of view in a case where the prodromal eruption was scanty and the true eruption was elsewhere copious. The termination was, however, favourable as in all the erythematous cases. It was somewhat different when hæmorrhage was present. As the parts where they usually appeared were the groin and the lower part of the abdomen, where the characteristic papules were least frequently seen, no influence on the true eruption could thus be said to be exercised. Thus among these cases a severe type of the disease preponderated, but in no case did the illness terminate fatally.

[1] Udoy Chand Dutt, Calcutta, 1877, p. 20.

BIRKENHEAD MEDICAL SOCIETY.—The seventh and last monthly meeting of the session was held in the society's library on May 8th. Due notice having been given the two following resolutions were considered and carried, the first unanimously and the second with two dissentients: 1. That in the opinion of this meeting it is unprofessional for medical men to serve any medical aid society in which touting is carried on, in which there is no wage-limit, and where money is funded by the society at the expense of the medical staff. 2. That in the opinion of this meeting the members of this society should refuse professional recognition of "sixpenny doctors" whether by meeting them in consultation or otherwise. The mover of the second resolution gave the following definition of "the sixpenny doctor"—viz., a medical man who openly or otherwise lets the public know that he will give them advice and medicine for sixpence, and will visit them for one shilling; or any medical man who has in that way commenced his practice.

LEWISHAM INFIRMARY.

A CASE OF PREGNANCY COMPLICATED WITH A PAROVARIAN CYST SIMULATING EXTRA-UTERINE FŒTATION.

(Under the care of Dr. F. S. TOOGOOD, Medical Superintendent.)

THERE are many cases on record of the complication of pregnancy by ovarian cysts, and in numerous instances the removal of the cyst has not exercised an unfavourable result, and pregnancy has gone on to the full term. The chief interest in this case is the resemblance which it appeared to have before abdominal exploration to a case of extra-uterine fœtation.

A married woman aged twenty-six years, who had not previously been pregnant, was admitted to hospital on Feb. 13th last complaining of abdominal pain. She brought with her a letter from the obstetric physician of one of the large London hospitals stating that he considered her case to be one of extra-uterine fœtation. She regarded herself as being four months pregnant, but stated that there had been some slight discharge at each of the missed periods. There was constant abdominal pain which had increased in severity during the last month. On examination the left part of the lower abdomen was found to be occupied by a soft elastic tumour reaching almost to the level of the umbilicus, which yielded no sounds whatever when examined by the stethoscope and phonendoscope. Per vaginam a rounded elastic swelling occupied the whole of the pouch of Douglas, while the cervix, which was pushed forwards and upwards, was firm, and the os, whilst rather large, was not patulous. It could not be demonstrated that the tumour felt through the abdominal walls was not the pregnant uterus or that there was any connexion between the above tumour and that felt in the pouch of Douglas. The patient was, however, anxious for operation, and on the 20th the abdomen was opened in the middle line and there were found a pregnant uterus and a parovarian cyst about the size of a cocoanut which was incarcerated in the pelvis and was pushing up the lower segment of the uterus. The cyst was removed without difficulty, the pedicle being transfixed and tied with silk and dropped back into the abdomen. The recovery was uninterrupted; she did not abort. The deep stitches were removed on the ninth day and the superficial on the fourteenth day. She got up on the twenty-eighth day, and, having been supplied with a belt, left on the thirty-fifth day, announcing her intention of returning there to be confined. Mr. E. R. Badcock, assistant medical superintendent, supplied many practical hints and assisted at the operation.

MILDMAY MISSION HOSPITAL.

A CASE OF LAMINECTOMY FOR PARAPLEGIA DUE TO SPINAL CARIES.

(Under the care of Mr. E. PERCY PATON.)

THE operator in this case is to be congratulated on not giving the account of the operation and its results when the improved condition of the patient may have appeared to warrant his so doing. The profession is thus enabled to judge of the case as a whole and appreciate it in all its bearings. Many cases have been published in which laminectomy for paraplegia depending on pressure on the spinal cord as the result of caries of the vertebræ has been performed with results which appeared at the time satisfactory, and have, as in this case, fully justified the operation. What is needed, however, is a record of the condition of many of these when some months have elapsed. This case shows the amount of repair which may follow the operation, also a possible reason for failure to obtain a more perfect result, although the condition of the cord as revealed at the necropsy suggests that it may have been damaged beyond recovery before the operation. So many cases of paraplegia due to spinal caries recover after prolonged rest that there is a natural desire to postpone operation as long as possible.

A boy aged eight and a half years was admitted to the hospital on Sept. 13th, 1894, with the history that during the summer of that year he was noticed to have some weakness of the left leg, which caused him to limp a little; but after a short time this improved and he was able to walk about quite well until five weeks before admission, when weakness and stiffness, with contraction of both legs, developed and confined him to bed. On his admission he was found to have a marked angular curve in the lower dorsal region (about the seventh, eighth, and ninth spines), with, however, no signs of pain or tenderness and little, if any, rigidity of the spine. Both legs were drawn up so that the thighs almost touched the abdomen and the heels the thighs. There was almost complete palsy to sensation and motion of both legs as far up as the top of both thighs, with much rigidity of both hips and knees; the knee-jerks were very active and ankle clonus was marked. Micturition and defecation were normal. No signs of psoas abscess were to be found or of suppuration anywhere else, or any signs of further tuberculous disease. During the next week or two an attempt was made to straighten the legs by a light weight and then to keep them so with splints. This, however, it was found impossible to do, as the slightest pressure on the legs produced sores almost at once. On Nov. 1st it was noted that the paralysis to motion and sensation had increased and was now complete to about the level of the distribution of the eleventh dorsal nerve, and that all reflexes had disappeared in both legs, and micturition and defecation were now carried out quite unconsciously. Also, the temperature had begun to be very irregular, but no sign of suppuration could be found. The above condition continued for the next two months without much alteration except for the fact that reflexes returned in both legs, which still remained drawn up against the abdomen. The temperature, however, kept very irregular, and as the patient was obviously rapidly going down hill it was decided to explore the cord by laminectomy. On Jan. 14th, 1895, a vertical incision was made over the seventh, eighth, and ninth dorsal spines and the laminæ of these vertebræ were rapidly exposed, the wound being stuffed afterwards with sponges to stop the bleeding, as recommended by Horsley. This was found very effectual, for on removing the sponges in a few minutes the wound remained dry. Two laminæ were now removed without difficulty by means of a saw and bone forceps. This was made much more easy by the presence of the angular curve. The theca when first exposed did not pulsate, but after a minute or two it began to do so. A careful examination now showed the dura mater to be covered by a moderately thick layer of granulation tissue, which was carefully dissected away. An exploration was then made of the posterior surface of the vertebral bodies with a probe, which resulted in the escape of a small quantity of caseous material, with a little pus, and as no more of this could be found and the patient's condition did not seem to admit of prolonging the operation the wound was closed with deep and superficial sutures, a fine drainage-tube being laid in it next the dura mater and brought out at its upper and lower angles. The patient rallied from the operation well, and the wound healed without any trouble, being dressed for the first time at the end of a week, the stitches being taken out then and the tube partly removed. Subsequently to the operation the general condition materially improved, the temperature being distinctly less hectic, also his appetite and general cheerfulness greatly improved; but with regard to the most important symptoms—namely, the paralysis—there was never any more than a partial improvement in sensation and power of movement in the lower limbs and in his control over the functions of micturition and defecation. On April 22nd a considerable abscess was found in connexion with the left hip-joint, which was opened, the joint being found to be completely disorganised and most of the head of the bone gone. It was found necessary to drain the cavity, which contained a large quantity of caseous masses, thin pus, and small pieces of carious bone. From this time the patient gradually went downhill and died on Dec. 12th, 1895.

Necropsy.—A post-mortem examination was made on

Digitized by Google

Dec. 14th, only the region involved in the laminectomy being examined. The wound was found to be soundly healed. The gap from which the laminæ had been removed was found much narrowed, and where no new bone had been laid down from the periosteum the space was filled in by very tough, resistant fibrous tissue, which formed a very efficient protection to the posterior aspect of the cord. On cutting through this scar there appeared to be some apparently recent clot around the theca, while on the right of it and pushing it over to the left was a mass of caseous material, which, on removing about three inches of the cord, was traced to a considerable caseous focus in the posterior part of the body of the vertebra just below the most prominent point of the angular curve. On the anterior aspect of the vertebral column was a similar caseous focus connected with the anterior part of the vertebral bodies. No pus had collected around either of these foci. The piece of cord removed was narrowed at the seat of pressure to a thickness rather smaller than that of an ordinary lead-pencil and its consistency was much tougher than usual, while the membranes around it were very much thickened and covered with thick tuberculous granulations. Unfortunately the piece of cord removed was spoilt for purposes of microscopic examination.

Remarks by Mr. PATON.—I have thought it worth while to record this case, though unsuccessful, as it is a complete one and the cause of failure to improve the paralysis was discovered at the post-mortem examination. This was no doubt due to the fact that the caseous material, which at the necropsy was found to have extended from the back of the vertebral bodies and in front of the cord to its lateral aspect, was already at the operation pressing on the cord in front, but had not extended far enough to be noticeable from its posterior aspect, at any rate, without a much more free removal of laminæ and more extensive interference with the cord itself than was done in this case. It seems difficult to see how a caseous collection in the bodies can be reached from the posterior aspect without damage to the cord itself, though Arbuthnot Lane seems to speak of it as comparatively easy. Chipault advises placing a hard cushion under the patient's shoulders and buttocks while his body lies prone and thus producing a general concavity of the spine backwards. He says that by this means the cord is rendered lax and can be hooked out of the way and so allow the posterior aspect of the vertebræ to be dealt with. Without having tried this device it would seem, however, that the nerve roots would prevent any considerable retraction of cord, even though it could be made sufficiently lax longitudinally. It would also seem that in a very much weakened column such as one has in a case of this kind, to put such an amount of strain on it as the proceeding above described entails cannot be done without considerable risk. The great mistake in the above case seems to me in not having made a sufficiently free opening into the spinal canal, though even had this been done it seems doubtful if much good could have resulted, and the general condition of the patient did not seem at the time to permit it. It is interesting to note at the end of eleven months how securely the posterior aspect of the vertebral canal was closed up with bone and tough fibrous tissue, and this even in a patient whose general condition was very unsatisfactory for sound repair.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The last meeting of the session was held at the Miller Hospital on May 1st, Mr. Ernest Clarke, President, being in the chair. The President delivered his annual address, the subject of which was the Various Manifestations of Eye-strain upon the Eye itself and the Bearing this has upon Treatment. He showed that the correction of ametropia was the essential part of the treatment of chronic or recurrent diseases of the eye, such as blepharitis, many forms of conjunctivitis, scleritis, iritis, and even glaucoma. He exhibited tables showing that in 200 eyes where cataract was present, in 150—i.e., 75 per cent.—there was astigmatism, and he showed that by correcting the ametropia in incipient cataract the advance of the disease might be averted or retarded.—Mr. Thomas Moore and Mr. Webster gave a demonstration of the Roentgen Rays.—Messrs. Johnson and Johnson exhibited a very fine display of Surgical Dressings and Plasters.—Messrs. Maw, Son, and Thompson showed a large Variety of New Instruments and Surgical Appliances.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Observations and Experiments on Intestinal and Gastro-Intestinal Anastomosis.

AN ordinary meeting of this society was held on May 12th, the President, Dr. W. HOWSHIP DICKINSON, being in the chair.

Mr. WALTER EDMUNDS and Mr. C. A. BALLANCE communicated a paper entitled "Observations and Experiments on Intestinal and Gastro-Intestinal Anastomosis." The object of the experiments was to determine the best method of uniting either bowel to bowel or bowel to stomach. The experiments were made on dogs. 1. Intestinal anastomosis: There were three main methods of uniting two pieces of intestine—namely: (*a*) side-to-side; (*b*) end-to-end; and (*c*) end-to-side. Transverse sections of human small and large intestine and also of dog's intestine were examined microscopically and measured, and it was found that while the intestine of the dog was more muscular than that of man, the all-important submucous tissue was of about equal thickness in the small intestines of man and dog, and somewhat thicker in the large intestine of man. (*a*) Lateral anastomosis: Various methods were tried—namely, Senn's plates, Davis's plates, Littlewood's plates, Mayo Robson's bobbin, Murphy's button, and Halsted's method of suturing. In the case of Senn's plates, Mayo Robson's bobbin, and Halsted's operations the animals did well; with Davis's plates and Littlewood's plates the experiments were not carried to completion. With Murphy's button the dog died from leakage because the button, which had been specially made for use in dogs from actual measurement, was very slightly too large for the dog in question; this, therefore, did not tell much against the button, but it indicated a difficulty that might arise in operations on man. (*b*) End-to-end junction. Of these methods there were tried Paul's tube, Jessett's tubes, and pure suturing both with Czerny-Lembert sutures and by Maunsell's method. The five cases done by the Czerny-Lembert sutures and the two by Maunsell's operation were all successful. By the former method a circular ridge was formed round the interior of the bowel which acted as a diaphragm and contracted the lumen. This circular ridge was absent after Maunsell's operation, but a longitudinal ridge was present at the site of the longitudinal incision, which did no harm. (*c*) Implantation of one intestine into another vertically. The two cases in which this was done (both by pure suturing) were successful. The conclusions arrived at were—(1) for lateral anastomosis Halsted's operation was best: a needle should be threaded at each end of each suture, the needles then had only to be passed in one direction; (2) for end-to-end suturing the most perfect result was obtained by Maunsell's operation, but the conditions would not always allow of its performance; and (3) for certain cases implantation was indicated. There were three main conditions for which these operations were required—namely, artificial anus from any cause, gangrenous hernia, and malignant disease of intestine. The enterotome appeared to have fallen into disuse in the treatment of artificial anus and the extra-peritoneal operation was only applicable to certain cases; the intra-peritoneal operation must therefore be used for the majority. This could be performed either by an end-to-end junction or by implantation or by lateral openings after inverting and closing the open ends. The last was considered the easiest and safest proceeding, especially if the surgeon had not much experience in intestinal surgery; and of the methods of effecting it Halsted's operation was preferred to Senn's. For end-to-end anastomosis (which was the ideal operation) Maunsell's operation was preferred to all those in which recourse was had to mechanical aids, whether of decalcified bone or of metal. The treatment of intussusception, gangrenous hernia, and malignant disease of the bowel was discussed; in the last the new growth should, if possible, be excised at the primary operation. Whether or not an attempt at reunion or anastomosis should now be made depended mainly on whether there was any chronic obstruction or not; if there was any to speak of the reunion should be postponed, because the passage of pent-up

Digitized by Google

fæces and the muscular action which this required were unfavourable to surgical repair. 2. Gastro-enterostomy: Operations were performed by pure suturing (Halsted's operation) and also by Paul's method with ivory rings. Both these methods were successful; their relative merits were discussed. 3. Physiological observations: (*a*) In lateral anastomosis the blind ends became shorter and probably would in time entirely disappear; the lateral opening gradually ceased to be lateral and tended to come more and more in the natural direction of the bowel. (*b*) In short-circuiting experiments the partially excluded portion, although not in any way occluded, became shorter and smaller. These short-circuiting experiments suggested a treatment for chronic volvulus; a lateral anastomosis would probably be more satisfactory than an artificial anus, and safer than total excision of the volvulus with reunion of the bowel. (*c*) In implantation experiments it made a difference whether the end of the upper bowel was implanted into the side of the lower or the reverse. In the former the blind end was small because the direction of its natural peristalsis was to expel its contents; in the latter case the cæcum was enlarged for the opposite reason. (*d*) In reversal experiments a length of intestine was completely turned round; the animals lived; the reversed portion diminished in length; there appeared to be some difficulty in the chyme entering the first part of the reversed portion; but the chyme once having entered it seemed to have passed along satisfactorily in the direction opposite to the original peristalsis. (*e*) Certain changes occurred in the mucous membrane in these experiments; above the seat of reunion the valvulæ conniventes disappeared for a time, possibly as the result of pressure. The paper was illustrated by numerous drawings.

The PRESIDENT observed that he had noticed the extraordinary healing powers of the intestine. In one case, probably of intussusception, a great length of bowel came away and the patient recovered. When a post-mortem examination was made some years later it was impossible to see which portion of the gut had separated.

Mr. GREIG SMITH (Bristol) said that he considered there had been no more valuable communication than the one before them made to the profession since Senn's work was first published. One important conclusion to which the writers had come was that it was best to avoid apparatus and he himself, from a different point of view, had arrived at the same conclusion. He based his opinion upon recent statistics which on this point were quite convincing. He considered the Halsted suture incomparably the best, as no infolding was necessary and it possessed great holding power. There was always a tendency for an anastomosis to contract or narrow, and no bobbin, plate, or button gave a sufficiently large opening, but by Halsted's method a very large opening could be obtained. He was convinced from a fairly large experience that resection of intestine for the closure of artificial anus was not now necessary. A sufficiently large external opening should be made through the skin muscles and fascia and then the peritoneum with its fatty layer should be left covering the bowel, which should be delivered through the wound with the handkerchief of unopened peritoneum attached to it. In this way the opening in the bowel could be closed without opening the peritoneum. For tumours of the intestine he preferred an operation of two stages, first delivering the tumour and fixing it out with a skewer and performing enterotomy and then in the second stage resecting the portion of intestine with the tumour. This procedure was troublesome to the surgeon, but had this peculiarity, that the patients all got well. Murphy's button was a marvel of ingenuity. It was said to produce what was euphemistically called pressure atrophy: this latter appeared to him to be very closely allied to gangrene. In two cases where Murphy's button was used he had seen alarming symptoms appear on the third or fourth day suggestive of gangrene of the bowel.

Mr. HARRISON CRIPPS, on the subject of bobbins and buttons as against fingers, repeated some experiences which he had related at the summer meeting of the British Medical Association. Of four fatal cases after the use of Murphy's button two died from causes unconnected with the operation, while the other two died from the button itself. In one the button has passed six inches below the junction and had ulcerated into the peritoneal cavity; in the other the button, which was still *in situ*, was probably too large, for it had caused gangrene of the bowel for an inch and a half on each side of it. He had found end-to-end approximation with Lembert's sutures the best. Of five cases four had recovered, and in the fatal one a double anastomosis had to be performed. He agreed with the last speaker that with apparatus it was impossible to make an opening sufficiently large to allow for subsequent contraction. In conclusion, he alluded to a successful case of gastro-jejunostomy by means of Murphy's button which had recently come under his notice. In using Lembert's sutures he applied them at a little more than one-eighth of an inch from the margin of the bowel, and this, he thought, prevented the infolding which had been illustrated.

Mr. LEONARD BIDWELL mentioned that a temporary fæcal fistula had occurred in each of three cases of Maunsell's operation which he had seen. He asked if Mr. Edmunds and Mr. Ballance had used a second row of sutures in the cases of Maunsell's operation done on dogs. In two cases of gastro-jejunostomy in which Mayo Robson's bobbin had been used there was after-obstruction due to the opposite wall of the jejunum occluding the lumen of the bobbin.

Mr. BRYANT remarked on the much greater thickness of the walls of the intestines in dogs; and a great deal of the ridge or diaphragm which was found after the Lembert suture was, he thought, due to this; one should be, therefore, very careful in applying these results to the human being. Unquestionably in some cases artificial appliances helped the surgeon very much. In one case he would have been unable to have completed a gastro-jejunostomy if he had not had a Murphy's button handy; but in that particular case on the fourteenth day something gave way and the patient died. At the necropsy it was found that the button had not come away and the junction was leaking at the upper edge.

Mr. EDMUNDS, in reply, said it was only because the end-to-end method of suture had proved so unsuccessful that other measures had been invented. The lateral anastomosis by Halsted's method was the best.

Mr. BALLANCE, in reply, said that they were agreed that the fingers were the best form of apparatus to use. In these cases the stitches were not placed far away from the ends of the bowel, and the same ridge occurred also in human intestine after the Lembert suture. They had also met with obstruction of the lumen of the bobbin from approximation of the side of the bowel.

MEDICAL SOCIETY OF LONDON.

General Meeting.—Election of Officers and Council.—The Connexion of Auto-toxis with Certain Common Forms of Insanity.

A GENERAL meeting of this society was held on May 11th, the President, Sir J. CRICHTON BROWNE, being in the chair.

The report of the council was read. It stated that 774 Fellows formed the membership, that the new laws had worked smoothly, and that the finance of the society was now fixed on a firm basis. The library committee reported that progress had been made in the cataloguing of the ancient books, and the house and finance committee stated that the property of the society was in thorough order and repair. A cordial tribute was paid to the energy and ability with which Mr. Hall, the resident librarian, had discharged his numerous duties during the year.

On the ballot being declared it was found that the following gentlemen had been elected to serve as officers and council during the ensuing year:—President: Reginald Harrison. Vice-Presidents: John C. Thorowgood, M.D., Charles B. Lockwood, Constantine Holman, M.D., and A. Pearce Gould. Treasurer: David H. Goodsall. Librarian: William Henry Allchin, M.D. Honorary Secretaries: George R. Turner and Robert Maguire, M.D. Honorary Secretary for Foreign Correspondence: Alban H. G. Doran. Council: John Anderson, M.D., C.I.E., Howard Barrett, William H. Battle, Frederick L. Benham, M.D., Robert L. Bowles, M.D., J. Mitchell Bruce, M.D., Henry H. Clutton, Sidney Coupland, M.D., Sir J. Crichton-Browne, M.D., F.R.S., Sir Dyce Duckworth, M.D., F. de Havilland Hall, M.D., Henry E. Juler, Norman Kerr, M.D., Jonathan F. C. H. Macready, Edward J. Nix, M.D., James W. J. Oswald, M.D., Heinrich Port, M.D., Amand Routh, M.D., Joseph White, and Arthur K. Willis.

At the ordinary meeting subsequently held a paper was

read by Dr. ALLAN MCLANE HAMILTON of New York, Corresponding Fellow of the Society, on the Connexion of Auto-toxis with Certain Common Forms of Insanity. The following is an abstract of this interesting communication. Dr. Hamilton said that until quite recently the therapeutics of mental disease did not appear to have been seriously influenced by the important researches that had been made during the last decade as far as deranged metabolism was concerned. He had been impressed with the somatic origin of various psychoses, especially those first classified and defined by Kraft-Ebing as acquired and by others ascribed to certain epochs, and he had looked for some more direct and reasonable cause than those ordinarily alleged to exist, reaching the conclusion that in many instances the existence of defective oxidation would explain the clinical features of numerous insanities formerly roughly classified with regard to their mental characteristics as mania, melancholia, and dementia, or still further particularised by names which defined their periodicity or the crisis at which they appeared or the element of hereditary predisposition, although in a few exceptions—notably, hepatic and rheumatismal insanities—the somatic element had been recognised. His desire for more exact knowledge in regard to the pathology and etiology of such every-day disorders as acute mania or melancholy was stimulated by the experience common to most, that where psychic causes existed not only the mental but the physical disturbance was usually quite out of proportion to any cerebral shock or demand upon the brain. It seemed to him that there must be something beneath this, something which had been simply lighted up or induced by the preparatory condition into which perhaps hereditary influences entered to some extent or not at all. With this end in view he had made a series of investigations, the results of which had been based upon experiments on animals and clinical observations conducted in the hospitals and asylums with which he was connected and elsewhere. More than fifty cases of insanity had been observed, which included examples of acute and chronic melancholia and mania; simple delusional insanities, primal and terminal; dementias; paralytic dementias; periodic, puerperal, and traumatic insanities; and the alcoholic and drug psychoses. The variation of the urine and fæces were noted. The experiments were undertaken to determine first whether there was any specific or noso-toxicity of the urine of the insane, and if so its nature; next to discover how important and general was the theory of uric acid poisoning; and, again, whether mental disorders were produced and modified by an autotoxæmia, whether the offending substances were the leucomaines or the intrinsic products of putrescence in the intestines. With regard to the existence of noso-toxosis observations on six patients proved negative and in rabbits the results were neither constant nor characteristic. The resulting effect seemed to depend upon the increased specific gravity of the urine and on the evidences of intestinal disorders and malnutrition. The urine of the paretic was always exceedingly toxic which property was possessed by that of the periodic patient whose urine showed a large amount of indican, while in only one of the other cases of mania in which the specific gravity of the urine was high was any result obtained by the injection. The only interesting psychic manifestation in rabbits which had received the injection of urine from a tabetic patient was a curious condition which led him to believe that hallucinations of vision existed. In respect of the influence of uric acid poisoning he was convinced that it had not as much to do with the genesis of mental disease as has been claimed for it. At his request Dr. E. E. Smith of New York prepared a quantity of hypoxanthin and with this was conducted a series of experiments on rabbits and monkeys. In only one subject were any effects produced. This monkey within five minutes manifested excitement, became restless, its ears became exceedingly congested, and its reflexes were affected by the slightest tap. After a time the irritability was followed by a period of apathy, its pupils were dilated, and the pupillary reflex was lost. These effects passed off in about an hour. It would appear that the intestinal toxalbumins had more to do with the production of disturbances of the nervous system than the leucomaines, which, however, had an effect, though not a marked one. A study of his cases unquestionably bore out the assumption that disturbances of the gastro-intestinal tract were attended by bacterial necrosis and the introduction into the general circulation of certain very virulent toxic agents whose effects were expended mainly upon the nervous system. A sudden and rapid development of incoherence, with mal-assimilation, highly-coloured urine, and delusions that were unsystematised clearly suggested an inquiry into the condition of the organs of digestion, and the first step should be a complete examination of the urine and fæces. It would appear that the ratio of the sulphates between themselves and the urea and the presence of indican in considerable amount were indications of intestinal putrefaction, which no doubt not only influenced the course of various insanities, but that a large increase in the combined sulphates had much to do with the genesis of various psychoses. In his opinion the presence of indican in the urine of the insane had the most significance, for in nearly all the cases that were not simply evolutional it had been discovered in excessive quantities in connexion with the development or as a feature of an exacerbation of an existing mental disorder. An excessive amount might be taken to mean any amount that could be detected in the urine by Jaffe's test. In melancholia the amount of indican depended upon whether the disease was of the stuporous or agitated variety, the quantity not being nearly so great in the former. In such cases the blood corpuscles and hæmoglobin seemed to undergo a decided diminution, which had been observed in other conditions in which anæmia existed in association with the increase in the amount of the combined sulphates and the presence of large quantities of indigo blue. The variations in the hæmoglobin and red corpuscles were closely associated with the absorption of toxic substances, the extent of which was announced by the increase of the combined sulphates, while the physical appearances were those of malnutrition. By far the most suggestive cases in which auto-toxis from intestinal disorder played a part were those of acute excitement, especially where there was rapidly developing incoherence and confusion. The more sudden and active the manifestations when unsystematic delusions or hallucinations were expressed the more positive were the indications of auto-toxis. He referred to the case of a woman aged thirty-seven who underwent an operation for the removal of a uterine fibroid, on the day following which she became restless and her temperature rose to 103° F. She had signs of gastro-intestinal disturbance and developed delusions and terrifying hallucinations of a persecutory nature, with broken and uneasy sleep. Her urine had a high specific gravity (1025); there was no albumin or sugar. The intestinal disturbance continued and was very general. Her incoherence almost amounted to delirium and she was greatly excited and restless. The urine showed a moderately large amount of indican with a lowered ratio of pre-formed and combined sulphates, and the urea was reduced to 11·81 grammes in the twenty-four hours. The administration of naphthaline, preceded by calomel and soda, determined a marked improvement in the mental symptoms, and the urine and stools returned to normal. In another case, that of a young married woman, examinations of the urine and excreta showed a very decided disturbance of gastric and intestinal digestion, and her general symptoms kept pace with the variations in these processes. The regulation of the diet, excluding nitrogenous substances, and thorough intestinal disinfection, together with the administration at regular intervals of calomel purges and a preparation of the red marrow of the small bones of the calf, brought about an almost immediately good result. Undoubtedly many puerperal insanities, especially those of the maniacal variety, were due to fæcal accumulation. Alcoholic insanities as well as other forms, whether acute or chronic variations prevailed, must, he was convinced, be studied with regard to the condition of the intestines. The insanity developing after very acute diseases, especially influenza, was probably primarily dependent upon the intestinal congestion and derangement of the mucous membrane, which was a part of the general disorder elsewhere, though in typhoid fever, where specific intestinal regions were attacked, there was apparently no undue amount of indican in the urine. The practical management of these cases not only included the provision of an absolutely suitable diet, but the use of antiseptics and mechanical means for the purpose of cleansing the gastric tract. It had been shown that the lower bowel was usually the seat of infection: hence the necessity of thoroughly washing out from as high a point as possible, using a long rectal tube. After trying a variety of intestinal antiseptics he had arrived at the conclusion that there was no agent which approached salicylate of soda. In insanity of a toxic nature there was considerable destruction of hæmoglobin and a reduction in the number of red corpuscles. He had had the

Digitized by Google

best results with a combination which was a rapid producer of nuclein, consisting of a mixture of a glycerine of the red marrow of small bones with bullock's blood. He formulated the following conclusions: (1) Urines rich in indican contained very little or no preformed sulphuric acid and were toxic; (2) when the sulphate ratio was materially changed it probably indicated auto-toxis in connexion with an increase in the amount of combined or ethereal sulphates; (3) such indications were generally found with acute insanities in which rapidly developing symptoms occurred; (4) fugaceous and changing illusions and hallucinations, unsystematised delusion, confusion, and verbigeration in connexion with insomnia, pallor, intestinal indigestion, constipation, and rapid exhaustion were due to auto-toxis; (5) paranoic states, or those in which concepts were the features, chronic stuporous conditions, and certain forms of dementia had little to do with the formation of intestinal products of putrefaction; (6) various post-febrile, traumatic, alcoholic, or drug insanities were those in which auto-toxis was most constant; (7) the variations in the excretion of combined sulphates kept pace with the changes in the progress of an established insanity, epileptiform attacks being directly connected with putrefactive processes; and (8) the most successful treatment consisted in lavage, intestinal douches, gastric and intestinal antisepsis by means of hydrochloric acid, borax, salicylate of soda, charcoal, guaiacol, or naphthalin in small and repeated doses, and the administration of a combination of the red marrow from the small bones, blood, and glycerine.

The PRESIDENT said that he welcomed Dr. Hamilton, in the name of the society, as a distinguished representative of American medical science, and he referred to the numerous and valuable contributions which he had made on the subject of mental diseases. His able, suggestive, and ingenious paper opened up much new ground, although most of it was of a speculative nature. In 1880 Lauder Brunton had pointed out the resemblance between the languor and dizziness of indigestion and the symptoms of curari poisoning, and had suggested that the symptoms of indigestion might be due to the absorption of peptones or of ptomaines from the intestine. They had only to suppose an excessive absorption of these substances or an imperfect destruction of them by the liver and they might arrive at the realisation of a condition tantamount to delirium with stupor or with simple dementia. These substances were present in great excess in intestinal catarrh and accounted for the melancholia present in that condition. The symptoms of these disorders yielded readily to suitable treatment, such as that in vogue at Marienbad or Carlsbad. It had been shown that an enormous quantity of fungi flourished in fæcal matter and that many varieties of fungi were only found in the fæces of certain animals. There were seventy varieties which were peculiar to the horse, thirty to the dog, twenty-eight to birds, and twenty-one to man. Any change in the quality of the fæces or of their environment might lead to the formation of an excess of poisonous products by certain of these fungi. Mosso had shown that a poison developed in nervous matter after death, and it was a question whether the brain could not form poison in itself during life. The epileptiform seizures seen in the later stages of general paralysis might be due to incipient decomposition of albuminous substances, and so an auto-toxis might be produced. Added to this it was well known that washing out the lower bowel alleviated these seizures. It appeared to him that the subject at present was one more for the laboratory than the wards, but the contents of the paper were worthy of the most careful study.

Dr. A. HAIG directed his remarks to the connexion which he believed to exist between the amount of uric acid in the urine and depression or melancholia. From his point of view the excess of uric acid in the blood caused the intestinal putrefaction, which he thus regarded as a secondary and not a primary factor. Calomel was an efficient agent in clearing the blood of uric acid and salicylate of soda did the same. Patients could be cured by altering the diet alone without recourse being had to intestinal antiseptics. The high blood pressure and the scanty urine present in these cases were both owing to the presence of uric acid in the blood.

Dr. W. L. ANDRIEZEN said that he agreed both clinically and pathologically with the conclusions of Dr. Hamilton. There was no doubt that such a common matter as a delay of the action of the bowels would produce headache, dulness, and depression of spirits in many people otherwise normal. He found this very difficult to understand on Dr. Haig's hypothesis; it was due rather to products directly absorbed from the alimentary canal. Leaving the lower bowel out of consideration and taking the stomach itself a great amount of poison might be produced in that viscus in cases of gastric catarrh. In certain cases of hysteria with dilated stomach, if the stomach were washed out and naphthalin in small doses were given a considerable and rapid improvement would usually follow. In hypochondriacal melancholia similar changes occurred, though longer drawn out. Those cases as a rule did not show hereditary taint, and that, so far as it went, was in favour of a local causation. In anæmia and chlorosis also depression occurred. He could not agree with Dr. Hamilton that all the subacute confusional manias of rapid development were of auto-toxic origin. He had examined instances of the insanities of alcoholism, general paralysis, and epilepsy in which from time to time mild attacks of subacute delirium occurred, accompanied by a slight rise of temperature and a furred tongue. In these cases a considerable excess of indican would be found in the urine at this particular stage. In such instances some might think that the primary cause of the transient disturbance was in the brain, and that the intestinal disturbance was a secondary result. He did not agree with that because of the immediate good result which followed the use of intestinal antiseptics. He considered that sufficient attention had not been paid to a group of insanities like those associated with myxœdema and acromegaly. In the insanity of myxœdema it had been found that treatment by thyroid extract caused a great improvement in the mental as well as in the bodily condition, and the extract appeared to exert a trophic effect upon the red corpuscles. The insanity of acromegaly was associated with mental slowness and depression with subnormal temperature, and in these the administration of pituitary extract did good. The question of the formation of alkaloids in the central nervous system must not be lost sight of; the cerebral lymphatic system was exceedingly complex, and there were marked perivascular changes in many nervous diseases, such as in alcoholic insanity; in these it was probable that the nerve cells were poisoned by retained lymph.

Dr. C. J. HARE said that he could not help being struck by the amount of knowledge which the ancients possessed, and the terms melancholia and hypochondriasis bore witness to the fact that they were alive to the idea of auto-toxis. It was certain that self-poisoning acted as a cause of many diseases other than mental ones.

Dr. THEODORE WILLIAMS said that if auto-toxis from intestinal accumulation were a common cause of insanity then the French nation should suffer much more than the English, for they were notoriously careless as to alvine evacuation.

Dr. DAVID BOWER said that he thought that intestinal trouble was more frequently the result of nervous disease than the cause. He regarded the suggestions for treatment as valuable. In the matter of intestinal antisepsis he thought it more rational to treat the matter as one of drains, in which one would remove the cause rather than conceal the smells.

Dr. HAMILTON, in reply, said he regarded his paper as a suggestive one. He believed that even gout had been given too much credit for its share in the causation of insanity. He believed also that in the majority of cases of acute mania some explanation might be found in the intestines if it were sought for.

CLINICAL SOCIETY OF LONDON.

Case of Malingering in a Boy aged Eleven.—Three Cases of Laryngectomy.—Case Illustrating a Condition of Partial Congenital Dislocation of both Hip-joints Forwards and Upwards.—Fracture of the Neck of the Femur in a Young Subject resulting from Dry Caries of the Bone.—Case of Division and Immediate Suture of the Left Vagus.

AN ordinary meeting of this society was held on May 8th, the President, Dr. BUZZARD, being in the chair.

Mr. LEOPOLD HUDSON related a case of Malingering in a Boy aged Eleven. He showed a specimen of urine coloured to imitate hæmaturia which was brought to the Hospital for Sick Children, Great Ormond street, on Feb. 17th, 1896, together with the boy, who was said to have passed it. The patient had been sent home from a boarding school on

Digitized by Google

account of hæmaturia. He remained at home for seven weeks, passing normal urine, but for the week previous to examination he was said to have passed blood in his urine three times daily. Examination of the urine showed absence of blood and albumin, it was acid and of normal specific gravity. Dr. Archibald Garrod made a spectroscopic examination, which revealed absence of the hæmoglobin band. Urine drawn off by catheter presented normal properties. Upon being pressed the boy confessed that he had added red sweets (jargonelle pear drops) to his urine. He had done this in order to be sent home from school, where he said he had been made to clean steps in cold weather without shoes or stockings. His story, however, was found to be false, for later his aunt brought to the hospital a piece of rag dyed with Turkey red dye which had evidently been used to produce the colouration.

Dr. E. WARD (Leeds) described three cases of Laryngectomy. He said that the main feature of the operation, which he had now practised in three cases, was the complete shutting off of the wound from the mucous canals which opened into it. This method in favourable cases resulted in union by first intention throughout the whole extent of the wound. No preliminary tracheotomy was required where it had not already been rendered necessary by urgent dyspnœa. The first part of the operation was carried out on the ordinary lines, the larynx being in preference separated by division of the crico-tracheal membrane and dissection from below upwards, enucleation of the upper part being thus facilitated. In cases of intrinsic disease the opening into the pharynx was not more than a small vertical slit. After the larynx had been removed a large tube was passed from the mouth into the stomach, and the cut edges of the pharynx were carefully brought together over it by closely-set sutures of fine silk, the pharyngeal wound being entirely closed. Then two half-discs of skin were cut out of the edge of the flaps opposite to the tracheal aperture, which was closely stitched to the circular opening thus made, and the skin wound was closed by suture throughout. Drainage-tubes were inserted at each end of the cross incision at the upper part. By this method of closing the wound the trachea and pharynx were completely shut out from it and the trachea was so held open that no tracheotomy tube was required. The œsophageal tube was removed or left *in situ* for feeding, according to the requirements of the case and the difficulty with which it was passed. Case 1.—A man aged sixty-four came with extensive disease of the larynx causing great suffering, dyspnœa, &c., and he was operated on on June 26th, 1893. He had remained well up to the present time and had never worn a tracheotomy tube. The growth proved to be a squamous-celled epithelioma. He was able to speak in a whisper. Case 2.—A female child aged two was admitted on June 2nd, 1894, with urgent dyspnœa for which tracheotomy was at once performed with great relief. The tube was removed on July 3rd, but had to be replaced on the 10th. In October thyrotomy was performed and the larynx was found stuffed with a soft papillomatous growth destroying all its anatomical features. This was scraped and dissected out. She remained in a very critical state for some time, though in November she had much improved. On Jan. 9th, 1895, she was readmitted extremely ill, the growth fungating so luxuriantly that it was sprouting through the tube and blocking it. He performed laryngectomy on Jan. 25th. There was some difficulty in closing the upper part of the pharyngeal wound owing to the smallness of the parts and their deep recession under the chin. The child was quite intractable and refused food, and she rejected what food was introduced by means of the œsophageal tube. She died in a state of collapse sixty hours after the operation. Post mortem the operation wound was found to be in an entirely satisfactory condition and the larynx was again crammed with papilloma. Case 3.—A man aged forty-two was admitted on Aug. 8th, 1895, with dyspnœa and dysphagia of five months' standing. He was extremely ill, with orthopnœa and marked stridor and lividity. There was much swelling of the ventricular bands, with general tumefaction of the whole of the parts, including the epiglottis, the vocal cords being quite hidden. No growth or ulceration could be seen anywhere. On Jan. 21st tracheotomy had to be performed. On Sept. 1st he was unable to breathe, the tracheotomy opening being plugged. The diagnosis was confirmed by a preliminary thyrotomy and Dr. Ward then performed laryngectomy. On the 17th it became evident that one or two of the sutures at the lower part of the pharynx had given way, but by the 21st the regurgitation of food had ceased. The patient's recovery was subsequently uneventful. Dr. Ward claimed for this operation (1) that it would reduce the mortality of the operation itself; (2) that it would considerably shorten the period of healing and convalescence; (3) that it would add immeasurably to the comfort of patients both during convalescence and after recovery; and (4) that it would justify attempts at radical treatment in some cases in which this was at present considered inadmissible.—Dr. FELIX SEMON said he did not consider laryngectomy an unjustifiable operation, but the whole case should be fairly put before the patient and the decision left with him. He protested strongly against the performance of laryngectomy for papilloma of the larynx, an affection which would yield to milder methods of treatment—namely, prophylactic tracheotomy with removal of exuberant papillomatous growth by curette. This would have enabled the child to live towards adolescence. When under partial chloroform narcosis and local cocainisation the growths could be removed by the intra-laryngeal route.—Mr. ARBUTHNOT LANE said that with regard to the first case he had adopted a similar procedure and found it useful—namely, turning the trachea forwards to an opening in the skin and shutting off the pharynx. In a case of papilloma of the larynx in a child aged seven he split the larynx up and removed the warts. There was an exuberant recurrence soon afterwards, and he then gave arsenic internally and pressed it. When he had got up to seven minims of Fowler's solution three times daily the growths withered and the patient got well very rapidly.—Dr. WARD, in reply, said that he was disinclined to attempt complete laryngectomy again in so young a child. He knew of three cases of papilloma of the larynx where tracheotomy with curetting and other local measures had been performed, and at the present time the larynx in each was absolutely blocked up with growth.

Mr. W. ARBUTHNOT LANE related a case illustrating a condition of Partial Congenital Dislocation of Both Hip-joints Forwards and Upwards. He showed a child on whom he had operated successfully for this deformity, with which he was familiar in a much slighter degree and often as a unilateral condition, but he had never before seen it in the same marked degree as presented by this patient. The deformity consisted in a varying degree of outward rotation of the legs, due apparently to a slight forward and upward displacement of the hip-joint from its normal position. In this case when the child lay on his back the feet rested by their outer margins on the floor. On attempting to rotate the thighs inwards it was only possible to do so till the inner margins of the feet became parallel to one another. The same was true of the child in the erect posture. During walking the legs were flung outwards and only very slightly forwards, so that progress was very slow and ungainly. Mr. Lane divided each femur at the junction of the middle and lower third, and after rotating the lower fragment inwards on the upper through an angle of 99° or more he secured them together with wire. The result, as exhibited by the patient, both as regarded locomotion and appearance, was very good. Mr. Lane pointed out that this partial displacement of the acetabulum, though produced during intra-uterine life, differed clinically from the cases of congenital displacement of the hip upwards and forwards where the head of the femur articulated with a new acetabular cavity, the old one losing its form rapidly. He ascribed the cause in both conditions to pressure, in one case resulting in a displacement of the head of the femur, in the other to a displacement of the hip-joint to a slight degree.

Mr. RAYMOND JOHNSON described a case of Fracture of the Neck of the Femur in a young subject resulting from dry caries of the bone. The patient, a boy aged seventeen, fell whilst skating, and presented all the signs of a fracture of the neck of the left femur. It was noticeable that during several weeks before the accident the boy had limped slightly and that his younger sister was the subject of early hip-joint disease. After a period of nearly four months' fixation there was no evidence of repair. Operation was therefore undertaken with the object of either pegging the fracture or excising the separated head according to circumstances. After opening the upper and posterior part of the capsule a transverse fracture through the middle of the neck of the bone was displayed, and as the bone showed evidence of somewhat extensive superficial caries the head of the femur was removed. Two and a half years after the operation the patient was walking fairly

Digitized by Google

satisfactorily; the shortening of the limb amounted to two and a half inches. After describing the naked-eye and microscopic appearances of the bone it was concluded that these were antecedent to and not the result of the fracture, and that they were of the nature of dry tuberculous caries. The chief interest of the case lay in the fact that such a degree of bone destruction should occur with so little impairment of function that the boy was able to skate without discomfort although the neck of his left femur was extensively carious. It was insisted that if in a young subject after an injury to the hip, and the symptoms suggested intracapsular fracture of the neck of the femur, the possibility of pre-existing pathological changes in the bone must carefully be borne in mind, even though the clinical evidence of such might be very imperfect.

Mr. MAKINS brought forward a case of Removal of a Secondary Epitheliomatous Tumour from the Neck, in which operation the left vagus nerve was divided just above the centre of its cervical portion and immediately sutured, with no obvious results either immediate or remote beyond the paralysis of the muscles supplied by the recurrent laryngeal branch. With regard to the laryngeal paralysis, the quality of the voice rapidly improved, and two months later the following report was made by Dr. Semon. The left vocal cord stood quite fixed near the middle line and the right joined it in phonation and the voice was almost normal, occasionally slightly hoarse and a little high-pitched. Apparently, after suture of the nerve the adductor fibres had partially recovered but not the abductor. After the partial recovery the adductor fibres had on phonation moved the vocal cord into the phonatory position, and in this position a gradual paralytic contraction had taken place, fixing the cord where it was now seen. It was allowed that the functional activity of the vagus in this case might have been lowered by continuous pressure by the tumour, but it was claimed that the case supported the opinion lately expressed by Boswell Park as to the comparative safety of dividing one vagus if necessary, and also offered some evidence as to the possible recovery of function if immediate suture were performed.—Dr. FELIX SEMON said that the partial recovery of function which had occurred was interesting. In cases in which paralysis of the recurrent laryngeal nerve supervened the abductor fibres suffered first and the present case acted as a kind of corollary to this, showing, as it did, that after complete division of the nerve the adductors recovered first. He referred to the case of a singer who acquired syphilis and a tumour formed in the neck which pressed upon the recurrent laryngeal nerve, inducing complete paralysis. Under appropriate treatment the adductors recovered, but the abductors remained paralysed. The cords at first assumed a cadaveric position, but later, owing to contracture of the unopposed adductor muscles, the affected cord became fixed in the middle line.

OBSTETRICAL SOCIETY OF LONDON.

Adjourned Discussion on Deciduoma Malignum.—Exhibition of Specimens.

AN ordinary meeting of this society was held on May 6th, Dr. CHAMPNEYS, President, being in the chair.

Dr. KANTHACK, at the request of the President, resumed the discussion. In all essential points he agreed with Dr. Eden's criticism. It was necessary to approach a question like this from the point of view not of the specialist but of the general pathologist. It was evident that the "deciduoma" is a malignant tumour. All are agreed upon that point; but some traced its origin to decidual cells, others to syncytial masses, and at least one other authority even to the connective tissue of the chorionic villi. On analysing the published accounts it would be found that, according to their nature, these deciduomas were either sarcomas, in which case they were said to have developed from the decidual cells, or carcinomas owing their origin to the syncytium. It was evident, then, that "deciduoma," apart from its hybrid nature, was a bad term, because it was not inclusive. He wished to suggest two other names to cover the carcinomas—viz., "syncytioma" or "trophoblastoma." He himself firmly believed that the deciduoma was a typical sarcoma, characterised by features common to many forms of sarcoma. It was certain that most of the deciduomas described or shown were sarcomas. He agreed with Dr. Eden that Dr. Whitridge Williams's specimen was an undoubted sarcoma and certainly not a carcinoma. Professor Spencer had described his case as a deciduoma consisting chiefly of syncytial masses, and he had laid great stress on the growth in the lungs. The latter was secondary to the uterine growth and certainly a sarcoma, and not even an extraordinary sarcoma. The uterine growths were curious, but presented nothing incompatible with sarcomas met with in other regions of the body. Mr. Rutherford Morison's case no one could consider anything else than a sarcoma, containing in certain situations large plasmodial cells (syncytial masses). Dr. Hebb's specimen, also, was acknowledged to be a sarcoma, the secondary growths in the lungs showing so-called syncytial masses. The plasmodial syncytial masses are said to be characterised by these three points: (*a*) absence of cell outline; (*b*) deeply staining nuclei; and (*c*) vacuolation. Now he (Dr. Kanthack) maintained that similar plasmodial masses formed by cell fusion occurred in many rapidly-growing sarcomas, and that it was illegitimate to argue from morphological analogy that these plasmodial masses are derived from syncytium. Some writers had described their specimens as sarcoma developed from decidual cells. The latter were connective tissue cells changed under the unknown proliferative stimulus of pregnancy. As Dr. Eden had well said, the decidual cell was not characteristic of pregnancy. It was necessary before calling a large-celled sarcoma a deciduoma that (1) pregnancy must be rigorously proved to have existed (this condition had remained unfulfilled in many cases); and (2) the pregnancy must have existed before the sarcoma appeared.

Dr. CLARENCE WEBSTER (Edinburgh), having expressed his pleasure at being able to attend the meeting, said that as he had seen no specimens of the so-called deciduoma malignum save those shown by Mr. Rutherford Morison and Dr. Spencer, he felt justified in limiting his remarks to certain points which he had noticed in his perusal of various published cases, referring in particular to some embryological considerations in which he was particularly interested. Like many others in this country he had been much surprised at the appearance of this new term. That the disease was of a malignant nature seemed evident; apart from the novelty of the name he did not think there was anything in the clinical symptoms which had not been before recognised in cases of primary malignant disease of the uterus. Nor was the connexion of malignancy with pregnancy or the puerperium anything unknown. The startling element in the new disease seemed to him to be in the pathology and etiology of the condition or rather in the discordant views expressed by writers. Thus the following statements are made as to the nature of the new growths—namely, that it is sarcomatous, that it is carcinomatous, and that it is made up of both sarcomatous and carcinomatous tissue. As to the tissue of origin of the new growth the following are mentioned: (1) maternal: epithelial elements of mucosa, connective tissue elements of mucosa, and muscle of uterine wall; (2) fœtal: epiblastic elements of villi, mesoblastic elements of villi, and combined epiblastic and mesoblastic elements of villi; and (3) maternal and fœtal elements combined. Taking together all the cases which have been published from the microscopical appearances described three distinct types are to be made out: (1) in some the tumour and metastases are composed of cells sarcomatous or carcinomatous in shape; (2) others are composed of cells as in No. 1 along with masses of plasmodial tissue like the syncytium found normally in connexion with the placenta; and (3) others are made up of the above constituents with the addition of villous structures exactly resembling the villi of the placenta as they are found normally or in the condition known as vesicular mole. The nature of the syncytium of pregnancy has been long discussed. Some state it to be formed from the epithelium of the uterine mucosa; others that it is a fœtal structure epiblastic in nature—the outermost layer, in fact, of the early ovum. The fœtal origin cannot now be denied. It has been clearly pointed out in different mammals, especially by Van Beneden and Hubrecht. The maternal origin of the syncytium was advocated in the days when there was no such careful technique in microtomy as is found at the present day. If it can be established that the syncytium found in connexion with these malignant growths is the same as that of pregnancy, and if it also be found in metastatic growths, it must be admitted that whatever be the origin of the other cells in the tumour the syncytial part is due to the malignant development of fœtal epiblast, parasitic on the uterine mucosa resulting from the product

Digitized by Google

of conception. However, another question is to be settled before such a conclusion is to be formed—viz., to what extent does plasmodial formation take place in connexion with the growth of sarcomata entirely unconnected with the influence of pregnancy? Dr. Kanthack states that this change is fairly common in sarcomata of different tissues of the body. This is an important point to establish in order to discredit a belief in the development of these tumours in the uterus from the syncytium of pregnancy.

Dr. W. E. FOTHERGILL (Manchester) said that most of the points in the pathology and literature of the subject on which he had any definite opinion had been referred to by Dr. Kanthack and Dr. Webster, with whom he completely agreed. He would like, however, to put in a broad and simple way the points in question. Of the twenty-eight or twenty-nine writers with whose work he was acquainted few agreed in opinion and still fewer used the same nomenclature. Some of them did not make it clear what they meant by cancer and sarcoma, and others did not even make any definite distinction between mother and fœtus. There are doubtless four tissues with which it is logically possible that the growths in question can arise—viz., from connective and epithelial tissue of the maternal decidua and from the epithelial and connective tissue of the chorion. Now malignant new growths arising from the decidual cells (connective tissue) are sarcomata and those arising from decidual epithelium are carcinomata (or epitheliomata or adenomata, as the case may be). Whether caused by pregnancy or any other circumstance most of the growths described are one or other of these or a mixture of both. There is no excuse for applying a new name to these, and the only result of their publication should be to attract attention to pregnancy as a factor somewhat overlooked in the causation of malignant change in the uterus. But if it can be proved that fœtal epithelium or epiblast can live and grow within the maternal tissues we doubtless have to do with a new pathological entity. Marchand raises hopes of a simplification when he says that all the forms recently described and variously named are derived from epithelium, but in another place plunges again into confusion by dividing this epithelium into two kinds, syncytium and the epiblast of the chorion. One observer only, Gottschalk, has stated that the fœtal connective tissue is concerned in the growths under discussion. The question at issue appears to be, Can fœtal epiblast, call it syncytium or what you will, form new growths in the uterus and produce metastatic growths elsewhere? At present there is no proof that this can occur. When it is found the new "chorionic carcinoma" will be welcomed, but not before. When it is recognised it certainly will not be under the deceptive and unnecessary misnomer "deciduoma malignum."

After a few remarks from Dr. LEWERS, Mr. BLAND SUTTON stated that his own views of this question were simple. He was of opinion that a deciduoma is a sarcoma arising in decidual tissue. Concerning other varieties supposed to originate in chorionic villi he preferred to maintain an attitude of active scepticism. Their occurrence was possible, but their existence had not as yet been satisfactorily demonstrated.

Mr. ALBAN DORAN maintained that Mr. Rutherford Morison's case was clearly an instance of the disease which the Germans term "deciduoma malignum," whatever the correct interpretation of that malady might be. Certain authorities seem assured that there was a true deciduoma malignum, but they had not calculated the chance of coincidence of simple sarcoma which occurred in young women with gestation. Yet Apfelstedt and Aschoff recently found vesicular mole tissue forming a secondary deposit in the labium three months after the expulsion of the mole from the uterus. Decidual tissue was hardly more complicated, its diffusion by metastasis was therefore conceivable. There had, on the other hand, been too much eagerness to make out decidual tissue in primary and secondary deposits. Thus, in the *Centralblatt für Gynäkologie* of May 2nd last two cases of deciduoma were reported. The patients were of the ages of thirty-eight and forty-two years respectively. Epithelioma was far more probable in both instances. The first case was described as epithelial cancer over twenty years ago, so that to re-classify it as a deciduoma was hardly scientific. In the second the uterus was removed nearly two years after the expulsion of a vesicular mole and there were no secondary deposits. The society could not admit that the existence of deciduoma malignum as distinct from sarcoma stimulated by gestation had been proved.

Dr. SPENCER thought that whether the disease belonged to the sarcomata or the carcinomata was a matter of slight importance; so also was the name by which it was designated. The really important question was whether they had to deal with an ordinary malignant growth in the uterus or whether they had to do with a malignant growth which developed from the products of conception (fœtal or maternal). He thought all the facts were in favour of this latter view.

Dr. EDEN said he was very glad to find that Dr. Kanthack and Dr. Webster shared the doubt he had expressed as to the identity of the plasmodial masses found in cases of deciduoma malignum with the placental syncytium. The question of identity depended upon one point—viz., whether the placental syncytium possessed any specific characters by which it could be distinguished from masses of nucleated protoplasm derived from different sources. He believed that it did not possess any such characters, and considered, therefore, that the plasmodial masses found in these growths could not be identified as syncytium merely from their microscopical appearances. If experience should prove that malignant growths consisting of proliferating placental villi may arise in the uterus and spread by the ordinary channels of metastasis, such tumours would form a distinct addition to pathology. It was obvious, however, that the term deciduoma malignum was quite an unsuitable designation for new growth composed of placental villi.

In closing the discussion the PRESIDENT did not doubt that the debate, which had brought much special experience tempered with general knowledge and a logical spirit to bear upon the subject, would prove useful. In reading the cases which had been reported he often wondered, as in the case of any other "new" disease, what such cases had been called before. He supposed, but was not sure, that most of them would have been regarded as forms of cancer or sarcoma. The conclusion of the debate seemed to be that the question is far from being settled and that it is yet too soon to add a new disease to the list.

The following specimens were exhibited:—

Dr. LEWERS: Two Uteri removed by Vaginal Hysterectomy for Cervical Cancer.

Mr. ALBAN DORAN: Cystic Myoma of the Uterus weighing over fifteen pounds.

Dr. ROBERT WISE: Placenta, Cord, Fœtus, and Membranes from Abortion of the Fifth Month.

Mr. MALCOLM: Two Solid Ovarian Tumours.

Dr. HORROCKS: Elastic Bags for Induction of Labour.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The Treatment of Whooping-cough.—Some Effects of Chronic Nasal Obstruction.—Exhibition of Patient.

A MEETING of this society was held on May 1st, the President, Dr. SYMONS ECCLES, being in the chair.

Dr. S. BONTOR read a paper on the Treatment of Whooping-cough. He pointed out that the death-rate from the disease was nearly as great now as it was twenty years ago, and said that although the malady was supposed to have a microbic origin its treatment was not based on that supposition; he therefore suggested the free use of antiseptics, both internally and locally, during the first stage. He considered that the second stage was due to a neurosis produced by the products of the micro-organisms and thought that the treatment should be directed to reducing the number and severity of the spasms and to loosening the mucus in the larynx and trachea. He had found the best method to be the local application of a solution of menthol in liquid vaseline. He had treated forty cases, mostly severe, in this way, with only one death.—Mr. MAYO COLLIER stated that the appearances of the larynx in whooping-cough were simply those of intense vascularity and congestion. He found that the only certain and efficient method of examining the larynx was to apply a spray of menthol in parolleum in which ten grains to the ounce of cocaine had been added.—Dr. CAMPBELL POPE recommended a thorough application of menthol spray to the nasal fossæ and pharynx, since the mucus which was the exciting cause of the spasms was probably formed in the nasal cavities.—Dr. CHAPMAN remarked on the use of the inhalation of chloroform in checking the spasms.—Dr. BURRELL had found small doses of antimony and morphia successful both for ordinary catarrh and for whooping-cough.—Dr. ACHARD recommended the fumigation of the

Digitized by Google

room with tar vapour produced by introducing a red-hot poker into liquid tar.—Dr. DOBSON experienced great difficulty in diagnosing whooping-cough from ordinary catarrh in the first stage, but he found that great benefit was derived from a menthol and cocaine spray in the later stages.

Mr. MAYO COLLIER read a paper on Some Effects of Chronic Nasal Obstruction, illustrating its serious effects upon the growing skull, especially on the upper jaw. The inevitable effect of nasal obstruction was the production of a partial vacuum in the nasal chambers, whose walls in the young were unable to support the increase of atmospheric pressure and consequently collapsed. In this way he explained the high palates, irregular teeth, and approximated maxillary bones, and the secondary almost complete obliteration of the nasal cavities. He showed several casts of the jaws of such cases.—Dr. THUDICHUM did not think that the mechanical pressure of the air was sufficient to distort either the septum or the maxillary bones, and considered that the casts exhibited were taken from congenital malformations and that the patients had only just escaped being idiots. He pointed out that hypertrophy of the inferior turbinated bone was the most frequent cause of nasal obstruction and referred to the good effects following its removal.—Mr. MCADAM ECCLES remarked that though adenoid vegetations were so common in young subjects the cases of deformity of the superior maxilla were very uncommon.—Mr. BATTEN had noticed a peculiar form of myopia as a result of chronic nasal obstruction.—Dr. CAMPBELL POPE and Mr. YEARSLEY also made remarks.—Mr. MAYO COLLIER, in reply, stated that the subjects from whom the casts had been taken were in no way mentally deficient, and said that the condition had commenced about the age of puberty. He considered that adenoid vegetations could not cause any distortion of the jaw.

Mr. KEETLEY showed a girl on whom he had performed a temporary Colotomy for Tuberculous Ulceration of the Rectum. He described the method of closing the artificial anus.

PLYMOUTH MEDICAL SOCIETY.

Exhibition of Specimens.—Testamentary Capacity.

A MEETING of this society was held on April 11th, Dr. HINGSTON, President, being in the chair.

Mr. C. RUSSEL RENDLE demonstrated: 1. A condition of Osteoporosis in a Femur and Tibia removed by amputation. 2. A Thyroid Dermoid removed from the coccygeal region of an infant when three hours old. The child was born naturally; the mass, which weighed twenty-six ounces, was attached by a fibrous stalk to the coccyx and a broad base lightly connected to the surrounding parts.

Mr. WEBBER showed a Microscopic Section of Fibroma of the Testis enucleated by Mr. Woollcombe.

Dr. ALDRIDGE read a paper on Testamentary Capacity, which was fully discussed and proved to be of great practical help and utility.

Exhibition of Specimens.

The closing meeting of the winter session of the society was held on April 29th, Mr. J. H. S. MAY being in the chair.

Mr. MAY referred in feeling terms to the great loss the society had sustained by the death of Mr. W. Square, who had filled the presidential chair in 1895, and who, by geniality and goodness of heart, had gained the affection of all the members.—Dr. ALDRIDGE and Mr. C. E. RUSSEL RENDLE also spoke as to Mr. Square's worth and great kindness to all with whom he came in contact.

Mr. C. E. RUSSEL RENDLE showed Sections of the Tibia and Femur removed from a boy aged seven years during excision for tuberculous disease of the knee-joint. There was a focus of disease commencing in the inner tuberosity of the tibia invading the joint through the cartilage. The cartilages on the outer side of each bone were sound.

Mr. LUCY handed round the skiagraph of a Hand and Forearm taken on a Thomas's antihalation plate with a Newton's "focus tube" and one minute's exposure by Mr. Oakley. The trabeculæ of the bones were plainly defined, as was also silk stitching of the coat-sleeve.

Dr. PETHYBRIDGE showed Tube and Plate Cultures of various Micro-organisms from Sea-water and the Intestines of a Fish.

Mr. WEBBER exhibited a section of the Thyroid Dermoid alluded to above.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Domestic Disinfection.—Criminal Responsibility in the Insane.—Village Water-supplies in Ireland.—Parknasilla as a Winter and Spring Health Resort.

A MEETING of this section was held on April 17th, the President, Dr. J. M. REDMOND, being in the chair.

Mr. WALTER BERNARD read a paper on the Necessity for Isolation and Disinfection when Infectious Diseases were being Treated, and he submitted models of portable apparatus for domestic disinfection of articles by heat and fumigation. One was adapted for the sick room and the other was reserved for the overalls worn by the medical man and the nurse. The apparatus was six feet long and thirteen inches wide, and could be carried from house to house. The articles were exposed for a considerable time to the fumes of heated eucalyptus oil and carbolic acid. Mr. Bernard at the same time called attention to the erection of houses, through building societies and other agencies, on polluted subsoil consisting of rubbish and street sweepings. He also said that the people are encouraged by burial societies to make false returns of ages and state of health; and, what is worse, a stone in the sleeve is hidden for the medical man who will not in the death certificate shorten the duration of the illness, so as to make it correspond with the statement of the person insured.

Mr. CONOLLY NORMAN read a paper on Criminal Responsibility in the Insane, first reviewing the history of the law on this subject and tracing the stages by which it arrived at its present position. He then pointed out the injustice and absurdity of the supposed legal tests of responsibility as applied to the insane, since a strict application of the criteria of knowledge of the nature of the act done or of knowledge of right from wrong would lead to all the insane being held responsible, with the exception of low-class idiots and a few acute cases. At the same time, he deprecated anything like an attempt at present to substitute medical for legal definitions in this matter. The knowledge of insanity is still so limited that we cannot define its conditions, and to endeavour to define that which is indefinable is to risk repeating the mischief already done and laying down criteria the validity of which will soon be as disputable as that of the former ones. Owing to a variety of circumstances there is not much, if any, practical injustice done under the present state of the law, however unjustifiable it may be in theory.—Dr. BEWLEY was glad to hear that Mr. Norman could not suggest any definite line upon which the law should be amended and that it was a mistake to define insanity. A little insanity and a great deal of wickedness and a little wickedness and a great deal of insanity merge very much into one another. Medical men are not always the best judges of insanity. They are too apt to believe that criminals are to be treated medically and not punished.—Dr. MCWEENEY wished to know in what position with regard to sanity or insanity Mr. Norman would place habitual criminals who from their very earliest days have a tendency to the committal of crime. When a person comes up for the eleventh or twelfth time charged with robbery, &c., the question should be taken into account whether the power of self-control has become so lowered that it could be said to no longer exist. A considerable number of the criminal population belong to this class, and a very important question is what is to be done with these people. A vast amount of money has to be spent in keeping them from doing harm.—Mr. NORMAN, replying, said that he thought the question as to the insanity of a criminal should be decided by a jury. The chief cause of complaint against medical witnesses arose from the circumstance that one judge wanted nothing but facts and another wanted the witness's opinions. The law regarding a lunatic giving evidence was much the same as that regarding a lunatic making a will. He could give evidence if he understood the nature of an oath and if he had not delusions on the point at issue. He could make a will if his memory was sound and he did not suffer from delusions with reference to his relatives or others that would be benefited by the will.

Mr. EDGAR FLINN read two papers—one on Village Water Supplies in Ireland and the second on Parknasilla as a Winter and Spring Health Resort. In the former paper he laid stress on the difficulty there existed in procuring a really pure and wholesome drinking-water in the smaller Irish

Digitized by Google

villages and towns, most of the wells being shallow and liable to pollution from surface and drainage percolation. The contract for the sinking of wells was nearly always placed in the hands of totally inexperienced and incompetent persons, who happen to have friends on the rural sanitary authority, the result being that in the majority of the villages the quality of the water is defective, and in dry seasons the supply is scanty.

Reviews and Notices of Books.

Manual of Gynæcology. By HENRY T. BYFORD, M.D., Professor of Gynæcology and Clinical Gynæcology in the College of Physicians and Surgeons of Chicago, &c. Containing 234 Illustrations, many of which are original. Philadelphia: P. Blakiston, Son, and Co., 1012, Walnut-street. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1895. Price 10*s.* 6*d.*

THIS book has been written with the intention of providing the student with a Manual of Gynæcology sufficient for "study or reference in his college course as well as a guide to him during his first years of practice." The subject matter is divided into ten parts, among which may be specially mentioned Part 7, consisting of five chapters on Genital Tuberculosis, and Part 10, on Ectopic Pregnancy, Pelvic Hæmatocele, and Pelvic Hæmatoma. The author has made use of two kinds of type with the view of simplifying the arrangement—a large type for what he considers to be actually essential and a small type for information on what he considers minor points of detail. On page 47 we notice an illustration of a syringe with an indiarubber tube attached which is recommended by the author for emptying the glass tube used in cases of abdominal section requiring drainage. We think the use of this syringe is objectionable in that occasionally the suction may cause portions of omentum to be drawn into the apertures generally found in the glass drainage-tubes employed. We think a better way is to empty the tube by means of a simple, long, narrow glass tube passed down to the bottom of the drainage-tube. We are glad to see that the author recommends in the section on Catheterisation that the nurse should expose the parts and disinfect them before passing the catheter. As regards the after-treatment of cases of abdominal section the author apparently only advises the patient being placed on her back if a drainage-tube has been used or if there is reason to fear hæmorrhage; in other cases he seems to be of opinion that she may be turned on her side from the first. This is certainly contrary to the practice usually followed and, in some cases at all events, it gives rise to a good deal of pain. He considers that Alexander's operation is the best one for cases of retroversion and retroflexion depending upon relaxation of tissue and unconnected with adhesions. As regards the treatment of carcinoma of the cervix, while the author states that the treatment most generally recommended at the present time is total extirpation by the vagina, he says it is probable that properly performed amputation of the cervix will in the near future be demonstrated to be equally effective for cases in their earlier stages. Many authorities in this country are of opinion that this has been fairly well proved at the present time.

The book is well printed and fully illustrated. Many of the diagrams, however, will be familiar to readers of other works on gynæcology.

A Manual of Pharmacology and Therapeutics. By WILLIAM MURRELL, M.D. Brux., F.R.C.P. Lond. London: Baillière, Tindall, and Cox. Pp. 657. 1896. Price 10*s.* 6*d.*

A SOUND and thorough knowledge of the action of drugs is of such great practical importance that the withdrawal of pharmacology as a separate subject from the examinations of the Conjoint Board should make no difference to the reception of a good text-book on the subject. Dr. Murrell's name is well known as a writer on drugs; in particular, his little work on the Treatment of Poisoning is known to every practitioner as a sound and practical treatise of the greatest value. The present volume maintains its author's reputation for practical knowledge and common-sense. Extraneous and unnecessary matter is for the most part avoided, and the pith of the subject is presented in a blunt and straightforward manner. After an introductory chapter dealing with various preliminary and accessory matters such as adulteration, modes of administration, dosage, tolerance, prescribing, &c., the pharmacology and therapeutics of the principal drugs are described in three sections under the headings of Inorganic Substances, Synthetical Compounds, and Drugs of Vegetable Origin. Its directness, plainness, and accuracy will make this, the main part of the book, very useful to the student. It is concluded by a good synopsis of pharmacological actions, tables of weights and measures, examples of prescriptions (in which the distinction between mixtures and draughts is not very apparent), a series of recipes for the "dainty dieting" of the sick, and a selection of examination papers for the guidance of the student. Misprints are unfortunately of frequent occurrence: such errors as "fibrilliary," "empyrematic," "guiacum," with many others are freely to be met with and should be corrected in the next edition. We have said that the directness and obvious intelligibility of style which characterise the book should commend it to the student. It is a pity that its plainness of speech occasionally degenerates into flippancy. We would also protest against the author's treatment of the subject of massage—a valuable remedial agent of which Dr. Murrell has himself written well elsewhere. Yet of three and a half pages on the subject he has here devoted no less than two and a half to a description which in our judgment is not edifying. It is to be hoped that these pages may be replaced in subsequent editions by a scientific account of the mode of action of massage and its special sphere of usefulness.

The Westminster Hospital Reports. Edited by R. G. HEBB, M.A., M.D. Cantab., F.R.C.P. Lond. Vol. lx. London: J. and A. Churchill. 1895.

THIS volume contains three "In Memoriam" notices, one of Dr. Sturges by Dr. H. B. Donkin, with a reproduction of an excellent portrait; one of Mr. Barnard W. Holt, by Mr. G. Cowell; and the third of Mr. W. H. A. Tebbs, by Mr. S. A. Bull. Mr. P. de Santi contributes a paper on Intubation of the Larynx, in which he discusses its usefulness and defines its scope. Mr. H. S. Fremlin writes on the Bacterium Coli Commune and its differences according to its origin. Dr. R. G. Hebb discusses the Fehling and Phenyl-hydrazine Tests for Sugar. Then follow cases of more or less interest by Dr. A. M. Gossage, Mr. P. de Santi, Mr. W. H. Gossage, and Dr. R. G. Hebb. A case of strangulated hernia is not usually looked upon at the present day (unless there is some unusual complication or pathological curiosity) as worthy of special mention, so we have naturally carefully read those published in some detail in these reports. We hope that few surgeons in the present day would go through the old-fashioned routine treatment described in one of hot bath, opium, and taxis, for a case in which the hernia was "well marked" and when the patient already had vomiting which is described as "fæcal." The description of parts sutured after the operation as "pillars of canal" is not easy to understand, yet it is important that it should be put more clearly, for in another case where a similar procedure was apparently adopted in May a note adds that the hernia had returned in October and produced symptoms of strangulation. Some of the medical cases

Digitized by Google

published appear to be of little interest as isolated cases, for instance, "phthisis with hæmoptysis" and "herpes of the mouth." From the careful medical statistical report of Dr. Gossage we learn that in 1893 1166 cases were relieved, 45 were unrelieved or transferred to the surgical wards, and 176 died; whilst in 1894 1130 were relieved, 72 were unrelieved or sent to the surgical wards, and 169 died. From the surgical report for 1893 by Mr. W. Wyndham Powell it appears that 1127 cases were relieved, 12 unrelieved, 5 transferred to the medical wards, and 54 died; from the surgical report for 1894 by Mr. P. de Santi it would appear that 1274 were relieved and 44 died, the general mortality being 3·24, as contrasted with 4·25 in the previous year. Mr. Frederick Moreton gives the reports for the department of diseases of women, from which we learn that the number of deaths in 1893 was 8 and in 1894 7. The reports of the post-mortem examinations for the years 1893-94 by Dr. Hebb may in time become of some value on account of their number, but so many are similar to the ordinary record that they are but slightly useful in their present form and could hardly be employed by anyone anxious to collect statistics without a reference to the original and fuller accounts of the necropsies. The volume ends with accounts of pathological specimens recently added to the museum, of the anatomical collection in the museum, of the proceedings of the Guthrie Society and of the Westminster Hospital United Sports Club. The volume is well printed and bound, but there is no index.

Syllabus of Gynæcology based on the American Text-book of Gynæcology. By J. W. LONG, M.D. Richmond, Professor of Gynæcology and Pediatrics in the Medical College of Virginia, &c. Philadelphia: W. B. Saunders, 925, Walnut-street. 1895. Price $1 net.

THIS little book has been written, according to the preface, with a threefold object; first, to be used as lecture notes; secondly, to enable the student more intelligently to follow and remember the lectures; and, finally, as a convenient reference for practitioners. It is based upon the American text-book of Gynæcology, which, the author patriotically believes, reflects the most advanced gynæcological thought and work. It really consists of a series of tables, and as there are several blank sheets between the tables we presume these are intended for such supplementary notes as may suggest themselves to the student. For our own part, we are inclined to think that the advantage of such a syllabus is to a great extent lost unless the student has evolved it for himself; otherwise it tends to become a sort of cram-book, which will infallibly be a temptation to the less industrious. We think it is a mistake to render the subject of gynæcology or, indeed, any other subject too easy, in the sense of attempting to afford instruction without the necessity of personal effort on the part of the learner.

LIBRARY TABLE.

The Housing of the Labouring Classes and Back-to-back Houses. By H. PERCY BOULNOIS, M.Inst.C.E. London: St. Bride's Press, Limited.—This is a reprint of some papers originally contributed to the *Surveyor and Municipal and County Engineer* and consists for the most part of a number of diagrams showing how the rooms in artisans' dwellings should and should not be arranged. As showing how rooms for the working classes have been, are, and may be planned, the pamphlet should prove of use, but the absence of technical details detracts greatly from its value for practical purposes.

Formulaire des Spécialités Pharmaceutiques à l'Usage des Médecins. (Formulary of Pharmaceutical Specialties for the Use of Medical Men.) Par le Docteur M. GAUTIER et Mons. F. RENAULT. Paris: J. B. Baillière et Fils. 1895. — *Mémento Formulaire de Poche de Posologie et Thérapeutique Infantiles. (Pocket Formulary of Infantile Dosage and Therapeutics.)* Par le Docteur H. DAUCHEZ. Paris: Société d'Éditions Scientifiques. 1895.—English readers of current French medical literature and also those practitioners who are likely to have foreign families among their patients will find both of the above-mentioned little books very instructive. The former of them contains much information on the subject of the numerous pharmaceutical preparations which are known either by the names of the original makers or by various fanciful designations, their approximate composition, dose, and the appropriate dilution of concentrated solutions being described. The selection of remedies used by French practitioners in the treatment of children's ailments contains some useful hints.

JOURNALS AND REVIEWS.

WE always turn with a feeling of pleasure and of anticipation of profit to the *Journal of Comparative Pathology and Therapeutics;* the March number affords ample justification for this feeling. The first paper by Professor Hobday on the Toxicological Effects of Creolin in the Dog and Cat is of sufficient importance to attract considerable attention. It has been very generally accepted that creolin is an absolutely non-irritant and non-poisonous substance, but from the experiments placed on record in this article it is evident that in the case of dogs, cats, and ferrets, at any rate, creolin is an exceedingly irritant substance when applied cutaneously and is capable of producing a paralytic condition, complete prostration, and ultimately death. Professor Hobday concludes that creolin is a narcotic and irritant poison to the dog and cat, and its use in these animals must be watched with the greatest care; that when spread in emulsions over a large area of the body it acts as a powerful irritant, the more refined samples acting more energetically than the less refined; and that it is not so readily absorbed from the stomach, from small wounds, or from the subcutaneous tissues as from a large area of skin surface. Of the toxic symptoms the most important are unsteady gait, especially affecting the hind limbs, and a sub-normal temperature, followed by complete paralysis, prostration, and clonic symptoms of all voluntary muscles, especially well-marked in the limbs, jaws, and eyelids; there is a stage of semi-coma followed by complete coma and death from collapse. Papers on Strongylus Tetracanthus Parasitism by Mr. Henry C. Wilkie, F.R.C.V.S.; on Canine Rabies in India, by Surgeon-Captain J. C. Vaughan, I.M.S.; on Enteritis in the Horse, by Mr. John Pemberthy, F.R.C.V.S.; and on Intestinal Psorospermosis in Lambs, by Dr. J. McFadyean, are given. This latter is accompanied by a series of excellent illustrations which give an exceedingly good idea of the pathological condition described. In an editorial article on the Stamping-out of Glanders it is pointed out that of the whole of the cases of glanders reported in this country 70 per cent. have occurred in London, and Professor McFadyean insists on the fact that it is necessary to do something to stamp out this disease, especially in London. He indicates the inefficiency of the means that have already been tried to eradicate glanders from London stables, and points out that the only possible means of getting rid of it is to regard every animal in a glandered stable as "suspect" and to insist upon the adoption of the mallein test (which is now recognised as being almost infallible) in every outbreak. He points out that in the long run this will be the most economical and satisfactory method, even if compensation for the horse and not a mere £2 for the carcase has to be given, and even if it is necessary to get a special Act of Parliament to carry all this through.

Digitized by Google

The initial cost and friction might be considerable, but the ultimate saving would be so enormous that it is well worth considering whether this should not be attempted at once. A number of clinical cases are also reported; a series of abstracts from foreign veterinary journals and a full abstract of Dr. Sims Woodhead's report to the Royal Commission on Tuberculosis complete this number of the journal.

In the *Veterinary Journal* for May the Essay on Immunity is continued, the author treating of Protective Inoculation against Quarter Ill, Pleuro-Pneumonia Contagiosa, and other cattle diseases, devoting special attention to swine plague. An article on Vivisection from the point of view of the veterinarian and the physician is a thoughtful contribution to the question. The number also includes an article on Scientific Breeding which may be of general interest, a number of Reports of Cases, and a protest against a paragraph in the Bill drawn up by Dr. Russell which places entirely in the hands of medical officers of health work which, it is alleged, can only be thoroughly done with the assistance of veterinary surgeons. In the work of the inspection of cattle in dairies it is probable that medical officers of health will be glad to avail themselves of the assistance of a veterinary surgeon. The remainder of the journal is taken up with proceedings of the Royal College of Veterinary Surgeons and the Veterinary medical societies, followed by abstracts from medical journals and reports of Parliamentary proceedings.

Analytical Records
FROM
THE LANCET LABORATORY.

(1) TABLOIDS: (*a*) OXALATE OF CERIUM, (*b*) CAFFEINE AND ANTIPYRIN COMP., AND (*c*) COMPRESSED OX-BILE; (2) SOLOIDS OF COMPRESSED CARBOLIC ACID.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, E.C.)

TABLOIDS of oxalate of cerium are of obvious convenience for administration in the class of cases in which the salt has been proved to be valuable. Cerium oxalate possesses, it is well known, tonic and sedative properties, and has been prescribed with excellent effect in acid dyspepsia, heartburn, &c., while in many cases it has proved beneficial in the treatment of the vomiting of pregnancy and of sea-sickness. Each tabloid contains five grains of the pure salt. The compound caffeine tabloids contain each one grain of caffeine and three grains of antipyrin, and are designed for use in many forms of neuralgia in which it is not advisable to give antipyrin without the addition of a cardiac tonic. The tabloids readily fall to powder in contact with water. The tabloids of purified ox-bile are keratin-coated, so that they are not dissolved until they reach the alkaline fluid of the intestine. In this way the irritating effect of bile on the mucous membrane of the stomach is avoided. They are prepared to supply any deficiency of bile in the system arising from hepatic disturbance or from obstruction of the biliary ducts. Bile is employed also as an alterative and as a laxative in chronic constipation and as a vermifuge in ascaris lumbricoides. The contents of these tabloids readily respond, we find, to the well-known reactions of biliary constituents. "Soloids" of carbolic acid are prepared in a shape which should be sufficient to distinguish them from a "tabloid" that is intended for internal administration. Furthermore, they produce a distinctive colour when dissolved which sharply marks the resulting fluid from any others that may be in use. Their sale should, of course—as we feel sure is the case—be rigidly restricted to the medical profession. The convenience of pure carbolic acid in this form is evident, since for use, for example, as an escharotic one soloid may be held in cotton-wool and gently rubbed over foul ulcers and suppurating surfaces, while when dissolved in five ounces of water a solution suitable for use as a disinfectant or antiseptic spray for application to the pharynx or larynx and nasal cavities is at once obtained.

IMPROVED BOVRIL (SPECIAL INVALID).

(BOVRIL, LIMITED, 30, FARRINGDON-STREET, E.C.)

Our analysis of this preparation, in the manufacture of which considerable improvement, it is stated, has recently been made, is as follows: moisture, 22·33 per cent.; organic matters, 63·83 per cent.; and mineral matter, 13·84 per cent. The organic matter (63·83 per cent.) was found to consist of albumin, 25·09 parts; peptones, &c., 24·57 parts; and crystalline meat principles, 14·17 parts. We have not examined a preparation containing so high a proportion of soluble albumin. It amounts to one-half of the matters precipitated by alcohol, the other half consisting of peptones; thus at least one-half of the original preparation is directly available as nutrient matter. The albumin is in a soluble state, but is coagulated on adding boiling water, the resulting fluid having exactly the appearance of beef-tea, containing the whole of the important fibrinous and albuminous constituents of prime fresh beef. These are balanced by the important stimulating extractives of beef. It contains in small compass all that is necessary to sustain the vital processes. Its flavour will be readily tolerated by invalids since it is of a pleasant "beefy" character.

"EXCEL" STERILISED MILK.

(THE "EXCEL" STERILISED MILK CO., LTD., 23, VICTORIA-STREET, S.W.)

On opening the bottle this milk was found to be in an excellent state of preservation, although it had been standing in a warm part of the laboratory for over two months. It was sweet and sound to the taste and had undergone no objectionable alteration. Our analysis gave the following results: total solids, 12·48 per cent.; solids not fat, 9·48 per cent.; fat, 3·0 per cent.; and mineral matter, 0·72 per cent. It was free from objectionable antiseptics, and, as will be gathered from the above results, is of uniform and good quality.

MEDICINAL MALT EXTRACT (EDME BRAND).

(THE ENGLISH DIASTASIC MALT EXTRACT CO., LTD., MISTLEY, ESSEX.)

This preparation proved to be a highly concentrated and active malt essence. It possesses a rich malty flavour and acts powerfully upon starch, converting it rapidly into maltose. It is, therefore, well adapted for use as an aid to the digestion of starchy foods, whilst furnishing also important food constituents.

PRESENTATIONS TO MEDICAL MEN.—Dr. John Martin has been the recipient from the members of the Huddersfield and District Teachers' Association Ambulance Classes of a Malacca cane and umbrella as a slight testimony of appreciation for his instructive lectures.—Dr. Patrick C. Pounden of Gorey, county Wexford, has been presented by his friends in the Killenagh and Wells Dispensary District with a gold watch, Albert-chain, and sovereign purse attached, as a wedding present, the watch bearing a suitable inscription.—Dr. C. R. Francis has been the recipient (on his resignation after thirty years' service as medical officer) from the residents of the Goldsmiths' Almshouses, Acton, of a testimonial consisting of a silk umbrella and an illuminated address.—Mr. Guy Mackeson, L.R.C.P. Lond., M.R.C.S. Eng., has received from the members of the Surbiton Ambulance Class a silver-mounted walking-stick inscribed as follows: "Presented to Dr. Guy Mackeson by the Surbiton Ambulance Class as a token of esteem, December, 1895."—Mr. E. E. King, M.R.C.S. Eng., has been the recipient from the members of the St. John Ambulance Classes, Ludlow, of a handsome silver teapot inscribed as follows: "Presented to Edward Ernest King, M.R.C.S. Eng., by the members of the Ludlow Ambulance Classes, April, 1896."

New Inventions.

A NEEDLE-HOLDER AND FINDER FOR VAGINAL, VESICAL, AND INTRA-ABDOMINAL OPERATIONS.

THIS Needle-holder, the illustrations of which are one-fourth the natural size, has the advantage of (1) holding the needle very firmly on account of the great force which can be used; (2) being suitably adapted to the hand; and (3) releasing the needle easily by pressure on the catch with the

FIG. 1.

FIG. 2.

little finger of the hand grasping the instrument. As a needle "finder" it will pick up a loose needle in a deep cavity owing to the magnetisation of the steel surface of the needle-grip (by placing it on a dynamo), and consequently is most useful in the above variety of operations. The original was made for me by Messrs. Ziemann and Co. of New York in 1889.

Christchurch, New Zealand. GRAHAM CAMPBELL, M.B.

SAFETY PARAFFIN LAMPS.

SINCE the report of THE LANCET Analytical and Sanitary Commission on Dangerous Paraffin Lamps appeared in our issue of Jan. 4th we have had brought to our notice various types of paraffin lamps which are claimed to be of a safe construction. We append a short description of each lamp with a few critical remarks thereupon.

Lamp No. 1, the construction of which is illustrated in Figs. 1 and 2, is known as the "Hydro Non-Explosive Hygienic Safety Lamp," and is the property of the "Hygienic Heating and Lighting Company," 13, Southwark-street, S.E. Its principal aim, which seems to us to be secured, is to prevent the production of a space above the oil in the reservoir as the oil is consumed, so that the formation of an explosive mixture of air and vapour in this space is obviated. This is accomplished, odd as it may appear, by first pouring in water in sufficient quantity and afterwards the oil. Fig. 1 shows the lamp after the water has been poured in and Fig. 2 the lamp with the oil added ready for use. The water need not be changed more than about once a year, so that in most cases it is only necessary to pour in the oil in the ordinary way Obviously this device ensures all the conditions of safety of a paraffin lamp. Thus, should the lamp be upset the water takes the place of the oil and the flame is immediately extinguished. Besides this the oil and the chamber are kept cool, while the reservoir is always weighted so that the risk of tilting the lamp over is very much reduced. It might be expected that the wick being liable to become wet would not

FIG. 1.

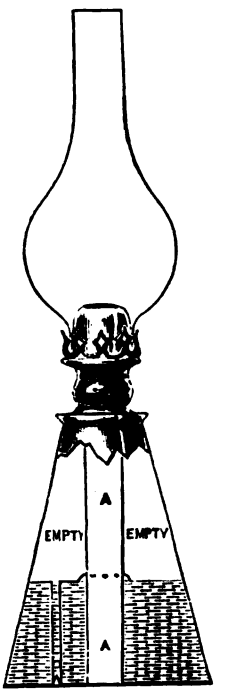

FIG. 2.

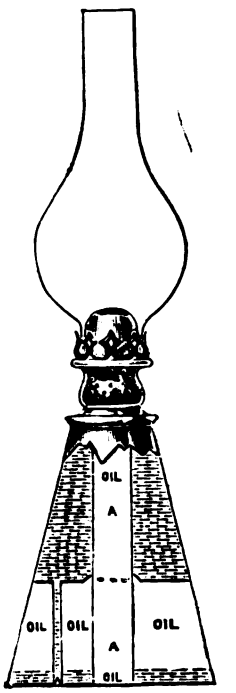
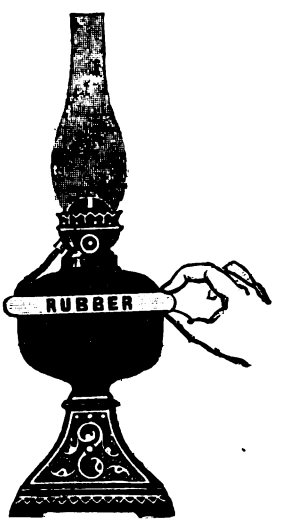


burn steadily. We have not found, however, any objection of this kind, as the lamp gives a brilliant, steady flame free from smoke and smell.

Lamp No. 2, the invention of Messrs. Stork and Lee of 70, Grafton-street, Leeds, exhibits no peculiarity of internal construction, but is provided all the same with a useful and probably safe device. It consists of either a self-acting extinguisher or of an extinguisher which may be used at will. In the former case, which is, we think, preferable, a ring

FIG. 3.

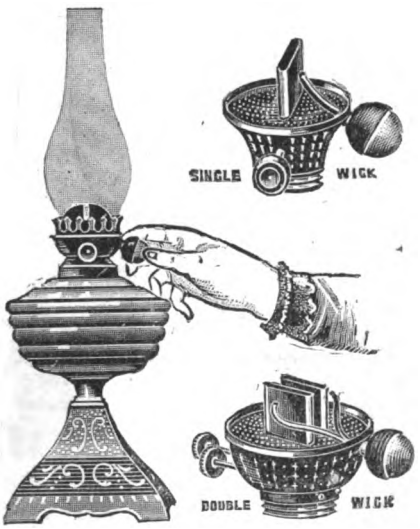


of rubber air-tubing is placed round the reservoir, a small rubber tube is joined at right angles with this and communicates with a small brass tube situated immediately beneath the wick. It is obvious that in the event of the lamp being upset a depression on the rubber tube is effected which causes a sharp puff of air to immediately extinguish

Digitized by Google

the flame. The accompanying illustration (Fig. 3) will make this action clear. Fig. 4 shows a similar device, applied to single and double wicks, which, consisting in both cases of a small air-ball, effects the same end. It is important to point

FIG. 4.



out that the air is directed upwards and not down upon the flame.

Lamp No. 3 is provided with a wick tube descending to within a short distance of the bottom of the reservoir. The wick tube is constructed so that it is impossible for the flame to travel down it, and there is no superfluous wick left loose in the reservoir. This, on the face of it, would make the wick too short, a drawback, however, which is obviated by attaching a small brass box at the end of the wick tube in which the wick terminates in a roll. In addition the box is closed underneath with a brass cap with a small hole in the centre through which are placed a few threads of worsted, which serve to supply the wick with oil from the reservoir. The lamp is, therefore, probably free from risk of explosion and from the ignition of oil when upset, so long, of course, as the screw fittings are good. The lamp is the invention of Mr. G. Holland of Barnton.

Lamp No. 4 is of simple construction, the wick, tube, and burner being situated some distance from the reservoir. The reservoir is pyramid-shaped, with a handle fixed upon it. A small pipe projects from beneath the reservoir to the wick-container, serving to feed the wick with oil. The wick-tube is in the same plane as the reservoir, but at a distance of about 2 in. from it. The lamp is proof against explosion and ignition of escaping oil. It is an inexpensive device, hardly artistic, but probably effectual, and is suggestive of a teapot with a vertical wick-tube attached to the spout. It is the invention of Mr. C. H. W. Remmett of 22, Edward-street, Camberwell.

Lamp No. 5 was sent by Mr. W. Heath of 21, Bride-lane, Fleet-street, E.C., and is simply fitted with an automatic extinguisher. The objection to extinguishers is their liability under constant change of temperature to become fixed, and therefore to fail at the precise moment they are required to act. The extinguisher of this lamp, however, appears to be very simple and is probably to be relied upon.

Lamp No. 6 is the patent of Mr. A. H. Thompson of 18, Garford-street, Poplar. We have not received a lamp for inspection, but it appears to be adapted for the burning of colza oil. It is stated that if the "Equipoise Lamp," as it is called, is knocked over by accident the flame is automatically extinguished.

Most of the above lamps were of an inexpensive type, and the chief objection to several of them consisted in their inferior screw fittings. This point was alluded to in the report of our Commission. The thread of the screw used for attaching the wick-tube to the reservoir is sometimes so badly cut as not to afford a safe means of securely fastening the wick-tube to the screw of the reservoir. In some cases barely the turn of the screw is necessary to detach it, with the result that on upsetting the lamp it is not improbable that the burner would fall out and the reservoir rapidly empty itself of oil. We have shown, however, that it is quite possible to construct a lamp which will not cost much and at the same time be safe, and there are plenty of devices which may be made to meet these ends.

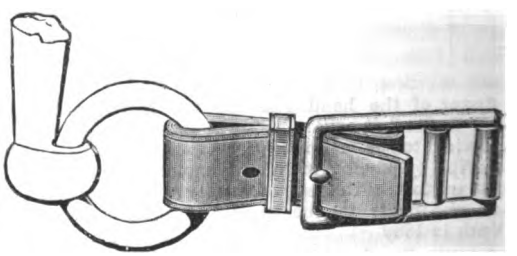
CATHODAL PLATES.

WE have received from Messrs. B. J. Edwards and Co., of The Grove, Hackney, N.E., a packet of cathodal plates which are specially prepared for the new photography in accordance with suggestions made by Professor Oliver Lodge. The sensitised film contains a fluorescent substance the presence of which greatly reduces the exposure—as we have ourselves found—while the pictures contain full detail with good density. We selected as a subject the elbow, and with a minute's exposure an excellent definition of the joint was obtained.

In this connexion we may add here that Dr. Macintyre of Glasgow writes that he has obtained very rapid results without the aid of fluorescent screens. He has found that by using a mercury interrupter the fluorescence obtained from the apparatus was more brilliant, while with the ordinary interrupter the current, although 17 ampères across the terminal screws of the primary wires, never rose to 1. On the other hand, with the mercury interrupter the actual current passing through the primary circuit registered as high as 5 to 7 ampères. This to a large extent explains the improvement which he has been able to note in direct vision as well as in reduction in exposures. He has also succeeded in obtaining shadows of the heart, diaphragm, and other soft tissues.

THE "RENSUM" PULLEY-REIN BRIDLE.

IN the interest of the profession, the owners of an army of horses, and of the public who look to them for guidance, we may call attention to the "Rensum" patent pulley-rein bridle for riding, driving, and schooling horses. This invention is intended to supersede the gag-snaffle for hunting and the gag-bearing rein for harness purposes and to give complete control over the most obstinate animal. The annexed diagram shows one of the pulleys, with billet for use on any



ordinary curb bit or double ring snaffle, either for riding or driving, and forms part of the "Rensum." Any apparatus which will stop a bolting horse with but little application of extra force must recommend itself; we need, therefore, only add that these bridles appear to have the high approval of the War Office. We think they are worthy of a trial. They are supplied by J. S. Rensum, The Cottage, Yardley, Worcestershire.

PATHOLOGICAL SOCIETY OF LONDON.—The following are the officers and council proposed for election for the year 1896. The ballot will be taken at the annual general meeting to be held on May 19th:—President: Henry Trentham Butlin, D.C.L., F.R.C.S. Vice-Presidents: William Richard Gowers, M.D., Samuel West, M.D., Norman Moore, M.D., Seymour Sharkey, M.D., Arthur E. J. Barker, Frederic S. Eve, Samuel G. Shattock, and Frederick Treves. Treasurer: Sidney Coupland, M.D. Honorary Secretaries: J. H. Targett, M.S., and Richard G. Hebb, M.D. Council: Wilmot Parker Herringham, M.B., A. A. Kanthack, M.B., Hector Mackenzie, M.D., Julius Dreschfeld, M.D., G. Newton Pitt, M.D., H. D. Rolleston, M.D., Charles Scott Sherrington, M.B., F. Charlewood Turner, M.D., A. F. Voelcker, M.D., Hubert Montague Murray, M.D., Gilbert Barling, M.B., James Berry, M.B., W. G. Spencer, Anthony Bowlby, E. Hurry Fenwick, H. Betham Robinson, Stephen Paget, Bilton Pollard, M.B., Raymond Johnson, and C. E. Leopold B. Hudson.

THE LANCET.

LONDON: SATURDAY, MAY 16, 1896.

THE constitution of the first Court of Appeal from the judgment of the General Medical Council cannot but be a matter of historical interest to the medical profession. The Court consisted of four members of the Privy Council—His Grace the Lord President (Duke of DEVONSHIRE), Lord RATHMORE (late DAVID ROBERT PLUNKET), Lord JAMES OF HEREFORD, and Lord MACNAGHTEN. No better Court, probably, of the sort could have been devised for the purpose. The wide experience of its members and the broad point of view from which they regarded the subject give importance to their judgment. It was easy to see that they were by no means intimately acquainted with the details of the Medical Acts and the interdependence under the Act of 1886 of the Medical Corporations. This is almost inevitable. If the General Medical Council has the wisdom so to administer the Medical Acts as to supply the material of an appeal only once in forty years it is scarcely likely to give their lordships of the Privy Council the chance of any serious familiarity with this somewhat technical and complicated legislation. The whole proceedings did not last more than about three hours. The statement of the case of the Apothecaries' Hall of Ireland by Mr. HALDANE, whose sound and studious knowledge of law is recognised, commenced the proceedings. He was supported and well prompted by Mr. B. S. FOSTER (son of Sir WALTER FOSTER), acting as junior. The case is doubtless well known to our readers, but must be recapitulated in outline; in fact, a similar outline occupied two-thirds of the time of the Privy Council on Monday. The Apothecaries' Hall of Ireland claims to be useful in a country which has some thousand dispensary officers, in supplying competent practitioners. Until 1886 the modest fee for its examination was 10*s.*; but by the Act of that year being unable longer to grant a separate diploma, it was required to be conjoined with another corporation or to seek the appointment of surgical examiners from the General Medical Council. The former arrangement was soon agreed to and a conjoint examination instituted between the Royal College of Surgeons in Ireland and the Apothecaries' Hall. This was a proof that in the judgment of those who knew Ireland there was room for an examination somewhat less costly, if not less exacting, than that held by the corporations of the King and Queen's College of Physicians of Ireland and the Royal College of Surgeons in Ireland.

The Conjoint Board of the Royal College of Surgeons and the Apothecaries' Hall seemed to work fairly well until very recent years, when the inspections of the General Medical Council showed less satisfactory results and the Royal College of Surgeons in Ireland saw fit to withdraw from a connexion out of which it probably drew a large share of the profits, and for the results and defects of which it must accept a large responsibility. Latterly the number of those receiving their diplomas from this Conjoint Board have dwindled down to a figure which, if permanent, would argue the superfluity of such a body. The College of Surgeons gave notice of the termination of its share in the conjoint examination in July, 1895, and then the troubles of the Apothecaries' Hall, whose conjoint examinations with the College of Surgeons had on three or four occasions been the subject of unfavourable notice by the inspector and visitor of the General Medical Council, became acute. The unfavourable notices applied chiefly to the medical part of the examinations and the climax was reached on June 6th, 1895, when it was resolved by the General Medical Council that the examinations having been found insufficient in four inspections, the General Medical Council "do now make a representation to that effect to the Privy Council." The representation was made to the Privy Council; but an easy answer was soon forthcoming. In August Sir C. LENNOX PEEL, in their lordships' name, replied that as the Conjoint Board was no longer in existence (having been terminated by the action of the Royal College of Surgeons in Ireland) it appeared unnecessary for the Privy Council to come to any decision as to the insufficiency or otherwise of the examinations. This was a sort of suggestion to the General Medical Council to consider *de novo* the question, but it was not so taken by the majority of the General Medical Council. And in November a request from the Apothecaries' Hall of Ireland to give that body another chance by appointing surgical examiners was rejected, leaving the Apothecaries' Hall no option but to appeal to the Privy Council, and this appeal came on for hearing on Monday, May 11th.

That the report of four inspections had been unfavourable and that a candidate—one of four—who really had done very badly in the examination in clinical medicine should have passed in medicine seemed facts rather damning to the Apothecaries' Hall; but this was not quite the whole truth of the last inspection, as was brought out before the General Medical Council and again before their lordships. The inspector and visitor did not deny that there had been general improvement in the examinations. They said so, indeed, in their report and added, "We have no fault to find with the examination itself." Mr. WHEELHOUSE, the visitor, with that candour which all who know him would expect, admitted that he was in error in saying that the candidate had passed. It was known that the candidate would be re-examined in the subject. Mr. HALDANE'S quiet statement on behalf of the Hall made the most of these admissions of the inspector and visitor. He showed that if the Irish members of the General Medical Council had not owing to unavoidable circumstances been absent the numbers on the division would possibly have been different. The statement of counsel occupied the Court till lunch time, and on its return Lord MACNAGHTEN, who had led their lordships throughout, suggested that it would relieve them from a delicate and difficult situation if the Apothecaries' Hall would approach the General Medical Council with another petition, leaving it a free hand in the selection of examiners, and if the General Medical Council would on its part entertain such

Digitized by Google

a petition. Mr. HALDANE undertook, after consultation with the representatives of the Apothecaries' Hall, to do so. Sir ROBERT REID was in a most difficult situation. He had not had the chance of stating the case for the General Medical Council; but in a few very apt sentences he vindicated the single desire of that Council to maintain a proper standard of education, and, though he could not pledge that Council, undertook to place the views of the Privy Council in a favourable light before it. The terms in which their Lordships spoke of the General Medical Council and of the respect in which it is held by the public show that they believed that it was a more fit body to decide such questions than the Privy Council. At the same time they hinted that there had evidently been a slight failure to allow sufficiently for the admitted improvements and for the actual facts regarding the candidate who did *not* pass. The result is not altogether unsatisfactory, although neither party to the appeal can be quite satisfied. But dispassionate critics will find little cause to grumble. The result is mainly gratifying as showing the reluctance of the Privy Council to interfere in questions for the settlement of which the General Medical Council exists. It is no doubt tempting to undo a Gordian knot by cutting it. But it is the English way to persevere, and if there be any reasonable ways of solving a difficulty to let no one remain untried. This appears to be the view of the Privy Council their lordships being evidently unwilling to interfere until every chance of settlement by the General Medical Council has been exhausted. This attitude of the Privy Council is a revelation that comes at an acceptable time, but we fear it will not be appreciated by the General Medical Council. This body has spent time, money, and energy in their attempt to raise the standard of the profession, and the Privy Council, with much politeness of phrase, recommend that they should reconsider their deliberate decision.

IN these days, when the evil of overcrowding in the profession is so apparent to ourselves, it is interesting to find that other countries suffer in the same way. The *American Medico-Surgical Bulletin* contains an article with the heading of "Recruits to the Medical Profession" in which some excellent practical hints are offered to recently fledged graduates. The writer asserts that, given good training, average ability, pluck, and stability, there is room in his land (America) for everyone. It may be noted in passing that these rather exceptional characteristics would command success in any walk of life. In addition, however, the possession of capital is insisted upon.

"It is the exception that a young graduate possesses at the start influence or help sufficient and of the proper calibre to enable him to start in life with a boom..... The road which the average new graduate will have to travel will thence be a very hard one, and without doubt many a one will drop at the wayside, weary of waiting and despairing of success, before the year is out. Let his comfort be that he thus is simply doing what scores of others have done in the years gone by. It is no reflection on his ability or on his merit. The result has been the necessary outcome of the fact that he adopted a profession without possessing the amount of money requisite to give him staying power during the early years of his struggle. In short, too many men undertake the study of medicine without being advised that there is no royal road to success, that the struggle is bound to be hard and bitter, that the competition is keen and is becoming keener every day owing to the boundless charity shown to the sick and the suffering, too often irrespective of their pecuniary status."

The last lines of this paragraph awaken thoughts that must be agitating the minds of many of the younger generation in this country as well as in America. There can be no question that were the circumstances of each individual patient at present under treatment in our London hospitals carefully investigated many would be found able to pay adequate fees for operation or other treatment. We cannot but think that the two main uses of hospitals—to relieve the really poor and to afford means of medical instruction—are far too much lost sight of in our large cities. Some of the special hospitals in the metropolis especially are so comfortable, not to say luxurious, that patients of the well-to-do classes have every incentive to enter them. And though we should be the last to discountenance comforts for the sick and needy, we question very much whether the funds subscribed by public charity should be expended in providing apartments and attendance fitter rather for the upper classes than the very poor. In our experience tradespeople are usually as well-to-do as medical men, and yet a large proportion of the former do not hesitate to accept public charity when occasion offers. We very much regret to have to point out that there is reason to believe that this unsatisfactory state of things is directly fostered by the want of business capacity and supineness of the members of the profession themselves. The practitioner in thoughtless kindness of heart says to his patient, "Oh, I will send you to Mr. X. at such and such a hospital, he will take you in and do it for nothing." Mr. X. is very commonly too kind and good-natured or too blind to his own interests and those of the profession at large to refuse. The patients like Mr. X., find him kind and "clever," and as a snug room is found for them at the "hospital" they gladly enter it and receive gratuitously the benefits of public charity and medical skill. The individual experience of many of our readers will supply them with instances of this undesirable state of things in sufficient abundance. We believe that the younger members of the profession, especially the consultants, attached to special hospitals would do well most carefully to consider their position and to absolutely refuse to confer the benefits of their services on any but the really poor. The spectacle of a struggling surgeon or physician conferring his services gratuitously upon the wife or near relative of a well-to-do tradesman would be ludicrous if it were not also sad and terribly incongruous. A firm combination should be entered into between general practitioners and consultants to resist by all means in their power the growing abuse of gratuitous medical work.

The article in our American contemporary goes on to give some excellent advice to young graduates regarding the subject of special practice:—

"Specialists are neither born to the purple nor are they made by three years' study. It is the acquisition of knowledge through years of personal observation and of practice which fits the average man for a specialty, and disappointment is bound to come to the graduate who, in forgetfulness

Digitized by Google

f this fact, at once after graduation announces himself as specialist in skin diseases, obstetrics, eye, and throat, or, a that very popular specialty, the diseases of women. If he scores of young graduates now being turned loose on his and other communities will only weigh well the question f adaptability to a special practice, they will reason out or themselves why it is a mistake on their part to rush into ne before they are really competent to cope properly with iseases of the body at large. This country now has far too nany *crude* specialists. It is they who cast disrepute on merican medicine and surgery. It is they who ruin the alue of our statistical data, reporting as they do incomplete nd immature operations, lauding to the skies new methods vhich their seniors in the profession would be desirous of esting for years before accepting as at all adequate or roper."

These remarks apply equally to our young graduates in his country. There is a regular rush into specialism. Attracted by exaggerated ideas of the earnings of specialists, nd with but a poor idea of their expenses and the requisite abours of their earlier years, "specialists" in the eye, ear, kin, or in the ever-popular gynæcology are almost weekly stablishing themselves in our large cities. Mr. MITCHELL BANKS alluded to this in his speech at the recent dinner of he Medical Society of London with some feeling. What is rue of London is true of Liverpool, and probably of Manchester and other large towns. "Incomplete and immature" perations are not unknown on this side of the Atlantic. Any young graduate who makes up his mind to become a "specialist" in any branch of medicine or surgery must also make up his mind to go through the many years of hospital drudgery that are essential to equip him with the superior knowledge, judgment, and skill that alone are sufficient to entitle him to the support of the members of his own profession and the public. It may be that hospital teachers are apt to neglect the opportunities offered to senior men to give words of counsel and advice to their juniors in respect of these and similar particulars.

A SPECIAL meeting of the governors of the Chelsea Hospital for Women will be held on Wednesday next, May 20th, at the Hospital, to adopt the following by-laws:—

"SUSPENSION.—A Member of the Honorary Medical Staff may be suspended from duty for not longer than one calendar month by resolution of the Weekly Board, and notice of a Special Council Meeting shall be immediately given to consider the case.

"REMOVAL.—A Member of the Honorary Medical Staff, whether previously suspended or otherwise, may be removed by a majority of not less than three-fourths of the members present at a Council Meeting specially convened by not less than seven days' notice, which notice shall state that the Meeting is to consider a matter concerning a member of the Staff. The member of the Staff in question shall have an opportunity of appearing before the Council to give explanations. A member so removed shall *ipso facto* cease to be a member of the Honorary Medical Staff."

The lay managers of hospitals have before now enacted by-laws offensive to their medical staffs, and it has been our experience that the more uncertain the status of the hospital, and the more undecided the reasons for its existence, the more is the lay management quick to misappreciate the relative importance of the medical and administrative sides of the institution. But for silly impudence manifested by a lay management towards their professional colleagues we have seen nothing to approach the two by-laws to which we give publicity above.

The weekly board of the Chelsea Hospital for Women is therefore to be given leave to suspend at pleasure a member of the honorary medical staff for not more than a month! This weekly board will attempt next to get a rule adopted enabling it to send cantankerous medical officers to bed not earlier than 6 P.M., or to fine them, say, not less than two pounds if they contradict each other in an angry manner. Seriously, however, these by-laws are an insult to the medical profession. If a member of the honorary medical staff does wrong of course he must be dismissed, but every properly constituted hospital, governed by persons able to look after its interest, has ordinary provision for this remote contingency. What do the lay managers of the Chelsea Hospital for Women mean by taking extraordinary steps and anticipating that their medical staff is likely to misbehave? These insinuations of bad conduct to be feared on the part of the medical gentlemen who do the work on the performance of which, we suppose, the hospital would base its reason for existence come with exceedingly bad grace from the lay board of the Chelsea Hospital for Women, who at the present moment rest under the stigma set upon them by an independent committee of investigation—we refer to the report of Lord BALFOUR of BURLEIGH'S committee. That committee, the members of which were Lord BALFOUR of BURLEIGH (chairman), Lord SANDHURST, Sir CHARLES DILKE, Dr. (now Sir) JOHN WILLIAMS, Mr. H. G. HOWSE, and Mr. J. H. BRASS, reported in July, 1894, that the administration of the hospital left much to be desired, that the Committee of Management did not meet sufficiently frequently, and that the house committee was scantily attended. In spite of these findings by an independent and unimpeachable body of gentlemen the lay board refused to resign and proceeded to elect a new medical staff. When they did resign later it was—according to Lord GLENESK, who tendered their resignation—for other and quite trivial reasons. Certain of the members of the old lay management were re-elected and remain active members of the present board. Would they have been re-elected if they had resigned when their conduct had been recently reviewed by Lord BALFOUR of BURLEIGH'S committee, and because of the findings of that committee? Of course not. In the eyes of all practical men the present lay management abides under the censure of Lord BALFOUR of BURLEIGH'S committee, and for it to take extraordinary precautions to censure other people is pharisaical and incongruous.

We have, in conclusion, one question to ask. Sir ALGERNON BORTHWICK (Lord GLENESK) on Nov. 28th, 1894, in tendering the tardy resignation of the discredited lay board, said that the question of mixed committees had been considered and that in the future the Committee of Management of the hospital would consist of laymen only; but it

Digitized by Google

would have attached to it, he added, one of the medical staff, who would always be ready to give advice to the committee, though he would not be a member of the committee or in a position to register any vote at their deliberations. Sir ALGERNON BORTHWICK then read out the names of the proposed new lay Board of Management, but he did not say who the medical adviser to this board was to be. He did not mention his name nor did he say how he was to be chosen. Now the offensive by-laws we have quoted have clearly a medical bearing. They constitute threats of punishment uttered by the lay management against the medical staff. If the purely lay board is suggesting out of their own lay heads that the governors of the hospital should adopt these by-laws they have acted improperly. But if their by-laws are the result of a consultation with their medical assessor we should like to have the name of the member of the staff of the Chelsea Hospital for Women who rates his colleagues so highly that he sanctions an attempt on the part of the lay management to make arrangements for having them whipped if they are naughty!

When going to press we hear that the full approval of the medical staff has been obtained to these proposals, but they could not have seen the drift of them.

THE Poor-law Officers Superannuation Bill as amended by the Standing Committee on Law has been issued, and since it will probably soon come on for the third reading, at which stage it may be expected that some amount of opposition will have to be met, it may be well to glance at some of the more salient points of the proposed measure. In the first place, it is very wide in its application in so far as officers and servants of Poor-law authorities are concerned. All persons regularly employed by such authorities, whether giving whole time services or part time only, come within the provisions of the Bill and will participate in its advantages. Thus superintendent registrars, district registrars, and school attendance officers come within the definition "officer." The managers of district schools, sick asylums, and the managers of the Metropolitan Asylums District also come within the purview of the Bill, their officers and servants being therefore included within the scope of its operations. As regards the "certainty" of superannuation which the Bill desires to see granted, it leaves it optional to existing officers whether they will accept it on the proposed basis, or by standing out from the enforced deduction of a percentage of salary place themselves at the mercy of boards of guardians and others in the matter of superannuation when the time comes for their retirement. In other words, if existing officers like to run the risk of a retiring allowance which is now at the discretion of their employers they may do so, just as they have had to do hitherto. If they decide to convert doubt into certainty they will have to pay from 2 to 2½ or 3 per cent. of their emoluments, according to whether they have been in office less than five, or less than fifteen, or upwards of fifteen years at the time of the passing of the Act. A superannuation allowance may be secured after ten years' service by reason of incapacity for discharge of duties arising from infirmity of mind or body, or of old age, or after forty years' service if the individual be sixty years old, or by having reached the age of sixty-five years; and the guardians may compulsorily retire an officer at the latter age if they deem it expedient. The allowance granted is to be at the rate of one-sixtieth for every year after ten years' service up to forty-sixtieths. All future officers and servants will have to surrender 2 per cent. of their emoluments to secure these benefits. All services, whether continuous or not, will be aggregated for the purposes of superannuation allowances, which latter will be granted on the average receipts of the last five years of service in each instance. Peculiar professional qualifications and special circumstances may, with the consent of the Local Government Board, be recognised by the addition of a number of years—not exceeding ten—beyond those actually served. Resignation of office, dismissal for grave misconduct, &c., may be followed by return of a part or the whole of the contributions made towards the superannuation fund; and an officer losing office through no fault of his own will have the right of return of his contributions and may be granted a gratuity in addition. But in all these cases of added years, of returned contributions and of gratuities, one month's notice of any such proposal must be given to each guardian. Certain provisions are made to meet the cases of appointments which lapse by reason of the death, or dismissal, or insanity, of one of two persons holding a joint appointment. The Bill also deals with the questions of divided unions, allowances to persons paid by fees, the inclusion for allowance purposes of all poundages, allowances for rations and house rent, and the like. It also appoints the Local Government Board as arbitrators in difficult cases, and finally limits the measure to England and Wales. Such, briefly, are the chief points of interest in the contemplated Act as at present drawn.

Annotations.

"Ne quid nimis."

SIR WILLIAM OVEREND PRIESTLEY, M.P.

THE unopposed election of Sir William Priestley to the representation of the Universities of Edinburgh and St. Andrews in the place of Sir Charles Pearson, the Lord Advocate, will be welcomed with satisfaction and pleasure by the whole of the medical profession. To us it is the more gratifying because the hope which we expressed in our issue of April 11th that the link which had so long bound the representation of the Universities to a Government office would be broken has not only been fulfilled, but fulfilled by means of the election of a medical graduate. Sir William Overend Priestley is the son of Joseph Priestley, the grand-nephew of the celebrated chemist; his professional qualifications and appointments are too well known to our readers to require recapitulation on the present occasion. The advantages which must result from the presence of medical men in the House of Commons are obvious, and, while congratulating Sir William Priestley on his election, we also congratulate the members of the House of Commons, whose hands will be strengthened when legislating on matters concerning the health of the public.

MEDICAL FREEMASONS.

THAT many members of the medical profession take an interest in Freemasonry is obvious for various reasons, among which the following may be noted. From time to time appear in our columns accounts of the meetings of the Æsculapius Lodge, which was founded for the convenience of medical Freemasons, and the members of which are, we believe, at the present time all medical men. The Rahere Lodge, if not entirely medical, being recruited from St. Bartholomew's Hospital, must be predominantly so. The University of London Lodge necessarily includes a very considerable proportion of medical graduates. And there is probably scarcely a Masonic lodge throughout the country which does not contain at least one medical practitioner. The important part played by members of our profession in the history of Freemasonry has been well shown by a distinguished Masonic writer, Mr. R. F. Gould, whose paper on the subject we reviewed in our issue of Jan. 26th, 1895 (p. 246). It is therefore deserving of record in THE LANCET that on the recent occasion of the twenty-first anniversary of the Prince of Wales's installation as Most Worshipful Grand Master of England high Masonic honours have been bestowed upon several medical Freemasons. Brother George Cowell, F.R.C.S. Eng., senior surgeon to Westminster Hospital, and Brother Henry Sutherland, M.D. Oxon., M.R.C.P. Lond., have received the honour of the rank of Past Grand Deacon, and Brother C. D. Hill Drury, M.D. Aberd., of Darlington, and Brother George Mickley, M.B., M.C. Cantab., Medical Superintendent of St. Luke's Hospital for Lunatics, that of Past Assistant Grand Director of Ceremonies. The number of those who received brevet honours on this special occasion was twenty-one, corresponding, we presume, to the number of years during which the Prince of Wales has been Grand Master, and it will be seen that our profession has received a generous proportion—nearly one-fifth of the whole number. We also notice in the list of the Grand Officers for the present year the name of Mr. Frederick Gordon Brown, M.R.C.S. Eng., L.S.A., who has been appointed one of the Assistant Grand Directors of Ceremonies. We congratulate our medical brethren (this last word ought to be as highly prized and respected in our world as it appears to be in that of Freemasonry) on their well-won promotion. Since the above was written information has been received of the death, at the great age of 106, of Mr. W. Salmon, M.R.C.S. Eng., of Cowbridge, Glamorganshire. It is hardly to be doubted, seeing that the date opposite his name in the Calendar is 1809, that Mr. Salmon was the Senior Member of the Royal College of Surgeons of England. The honour was also generally claimed for him of being the oldest Freemason in the world, although the validity of this claim has, we believe, been questioned in the Masonic papers. Be this as it may, we may safely look upon him as having been the oldest medical Freemason.

PRECAUTIONS AGAINST RABIES.

IT is a pity that some more efficient methods cannot be taken for the extinction of rabies than those at present in vogue. The muzzling order as it now stands is very incomplete, and by its incompleteness it not only fails to effectually stamp out the disease, but also gives rise to great dissatisfaction on the part of those who keep dogs. It is quite absurd to muzzle dogs in a certain small district and limit it by definite lines, and this is pointed out in our last week's issue by our correspondents in Manchester and Ireland. At Dublin, for instance, we are told that while the South Dublin Union approves of muzzling the northern part does not, so that the consequence is that people remove the muzzles as soon as they pass over the boundary line. Such local laws are, of course, absolutely worthless and most illogical. We further learn from one of our correspondents in Ireland that a member of the profession has been strongly protesting against muzzling dogs, as in his opinion it is calculated to produce rabies and to develop in rabid dogs a tendency to bite, and also, in this gentleman's opinion, a muzzle may actually cause madness, and so rabies may develop *de novo* without contact with another diseased animal. We cannot agree with him in this theory and we cannot help thinking that a great deal of harm may be done by the spread of such ideas. If efficient muzzling were enforced throughout the country for a certain time and proper precautions taken with regard to imported dogs there is no reason why rabies in England should not become a disease of the past. The objection to muzzling is mainly the result of a morbid sentiment which considers the temporary inconvenience caused to the dogs to be of more importance than many human lives. One great good the order has certainly done: it has shown what a vast number of dogs there are which are never looked after, and the destruction of many of these has at least removed some of the dangers and nuisances which they cause.

BICYCLING FOR WOMEN.

THE April number of the *American Journal of Obstetrics* contains two articles on the question of bicycling for women. One of the papers was read before the Washington Obstetrical and Gynæcological Society by Dr. F. S. Nash in December last, and the same number of the journal contains a short report of the discussion which followed the reading of his paper. The opinions expressed in these two papers and in the discussion mentioned appear to be on the whole distinctly favourable to the use of the bicycle by women. At the same time the possibility of harm resulting was not lost sight of. It may not be out of place for us to briefly consider some of the dangers that have been suggested as likely to result. The advantages are so much in evidence that we need say very little about them. It is rather in the direction of pointing out the possible dangers that we think it may be useful to make a few observations. As regards the effect of the bicycle on the pelvis, it is to be borne in mind that the pelvis is not really mature until at least twenty years of age. Before that time its shape is decidedly influenced by pressure. One of the objections urged to the use of the bicycle has been that the tuberosities of the ischia may be pushed upwards and inwards, so as to seriously curtail the transverse diameter of the outlet of the pelvis. This view takes for granted that the rider uses a saddle that enables her to support herself actually on the ischial tuberosities, as in ordinary sitting. On the other hand, it has been urged by Dr. Nash that so long as the patient is really supported on the saddle by the ischial tuberosities alone without pressure on the perineum no harm is likely to result. It will thus be seen that those who have given careful consideration to the subject are by no means in accord in their views as to how immunity from ill-effects in bicycling may be best secured. Under the same circumstances one writer says that contraction of the pelvic outlet in the transverse diameter will result, a consequence that may be of the gravest import in a subsequent labour, while another takes the view that nothing of the kind is likely to happen. This being so, we must probably wait for further information as the result of actual experience before this and allied questions can be satisfactorily settled. In the meantime it would seem desirable that young girls especially, whose pelves are not firmly ossified, should either be advised not to use the bicycle at all, or at any rate to use it to a very moderate extent. Some of the cases in which the use of the bicycle is likely to be advantageous are those of hysteria, neurasthenia, anæmia, chlorosis, dyspepsia, constipation, or in general terms cases

Digitized by Google

where the patient is more or less an invalid, but without the existence of any definite organic disease. We have already called attention to the opposite opinions as to the effect of bicycling on the pelvis. We may also mention that authorities are equally divided as to the effect of bicycling on the perineum, some holding that the effect of bicycling on the perineum is to render the structures of the pelvic floor dense or, indeed, almost cicatricial, and therefore extremely slow and difficult to dilate; while others hold that the effect is the exact opposite, and that, in patients who ride bicycles, the perineum actually dilates much more readily, so that the latter part of the second stage of labour is materially facilitated. There can be no doubt that bicycling during a menstrual period is unadvisable, and that to ride during pregnancy will in many women involve a special liability to the occurrence of a miscarriage or of premature labour. From what has been said it is evident that ill-effects due to bicycling may be immediate or remote. Among the more serious of the immediate consequences are the production of ante-partum hæmorrhage, or the derangement of the function of menstruation. A less important immediate consequence may be abrasion of the skin of the perineum and parts adjacent; this may probably be avoided by choosing a good form of saddle—one that presses as little as possible on the perineum. The most serious remote consequence that appears to be possible is deformity of the pelvis. At present we do not think that the occurrence of such deformity as a result of cycling has been actually proved. We publish in another column an interesting article on Perineal Pressure in Cycling by Mr. A. C. Roper. His paper is more especially concerned with the effects of cycling in men. In the concluding paragraph, however, he makes a few remarks on cycling for women, and expresses the opinion that women are less liable than men to damage from pressure. We should be disposed to take exception to this opinion. It is true, as Mr. Roper says, that in women the urethra is not much exposed to pressure and they have no prostate to be bumped about. There is, however, the effect of pressure on the shape of the pelvis to which we have referred above which has especial importance in women; and, again, if they have no prostate there are the uterus and vagina which may be displaced or prolapsed, and there are the uterine appendages which are prone to inflammatory mischief. An old-standing perimetritic inflammation may easily be stirred into renewed activity by over-exertion or imprudence, especially at or about the time of a menstrual period. We should say that there are many more possibilities of harm resulting from cycling in the case of women than in the case of men.

THE REFORMATION OF BABY-FARMING.

THE horrors which have recently come to light in connexion with baby-farming must have convinced the most indifferent observer of the necessity for employing such measures as will not only threaten, but effectually prevent, the recurrence of such barbarities. To punish the criminal is just; it is wise, also, because in some degree deterrent; but the crimes themselves, for these are but representative of a class, prove that the remedy remains to be discovered. In order to find this we must be familiar with the conditions under which the system of foster-parentage commonly maintains itself in the present day. Such conditions in very many cases are merely the effect of a too selfish regard for domestic or personal convenience. A child for some reason, usually because it is expensive or illegitimate, is considered to be superfluous and it is boarded out. The transfer is regarded as a confidential matter and is conducted as a rule with all possible secrecy. The result may be favourable to the child. In many cases it is so, for the transaction may be of a *bonâ-fide* character. In many more it is quite otherwise. After a few months it ends with the child's death, and for some impoverished parent or unwedded mother there is one incumbrance the less. To question the existence of criminal complicity in a large number of such cases would be to ignore the most patent facts of legal evidence. As to the means employed these are not always summary and certain, though the more gradual process of starvation is hardly less effectual in the end than actual violence. Wearing, as it may do, the comparatively innocent aspect of an error in judgment it is, on the whole, safer—or at all events it is supposed to be so. In judging of its real character and motive there is need of the careful examination of circumstantial data. It is only after a scrutiny of these various facts that we can find ourselves in a position to discuss the question of preventive treatment. To our own mind this does not present any very serious difficulty, but it requires to be dealt with in a decided and practical manner. We have always maintained that inspection is in such cases the key to the position but this method in order to succeed ought to be carried much further than it now is. It should be made to apply to the case of every single infant sent away from the parent to be nursed. It should take cognisance of the character of the intending custodian, of her fitness for her duties, and we may add, of the health, condition, and prospects of the infant. It should provide for periodical official supervision of the nurse and child. It would also be desirable as a safeguard, and a very simple matter, to provide the nurses with a code of instructions as to necessary points in diet and hygiene. Hitherto the State, beyond instituting a system of partial registration, has made no regular provision for the requirements of nurse-children. We trust that the evidences of legislative inadequacy which from time to time have been so painfully apparent will at length, and soon, receive that practical recognition which can alone make amends for past neglect in reference to this subject.

THE ADMINISTRATION OF THE VACCINATION ACTS IN THE COUNTY BOROUGH OF READING.

DR. ASHBY, medical officer of health for Reading, has just issued a special report on the vaccination of this county borough, and the document has interest from several points of view. Dr. Ashby first shows that the increase in the number of children unaccounted for as regards vaccination had risen from 2·0 per cent. of registered births in 1872 to 24·4 per cent. in 1894, and he calculates that this represented a remanet of 26 unvaccinated infants for 1872 and 231 for 1894. This rate of increase must mean for the period in question between 1000 and 2000 children who have no protection against small-pox. Another point well worthy of notice is the fact that certificates of so-called "insusceptibility to vaccination" are on the increase in the borough. As to this he recalls the statement in Dr. Thorne Thorne's last report to the Local Government Board, to the effect that in the hands of the several vaccinators attached to the Board's Vaccination Department there have been, within a certain term of years, over 81,500 consecutive vaccinations of children, either from arm-to-arm or from calf-to-arm, without the occurrence of a single case of "insusceptibility." And he further records that in the hands of the Public Vaccinator of Reading precisely the same result has been obtained as the result of 14,000 primary vaccinations. The obvious lesson is that insusceptibility must be regarded as all but non-existent when vaccination is performed with fresh lymph in either of the methods referred to, and that it is essentially a product of vaccination with stored lymph. And if the use of stored lymph leads so often to absolute failure at all insertions made, and this on the three consecutive occasions which alone constitute statutory insusceptibility, how

Digitized by Google

numerous must be the occasions where one or more out of several insertions fail and only a partial protection is granted? Lastly, Dr. Ashby properly protests against the position in which a borough such as Reading with its 60,000 population is placed by the delegation of vaccination to the guardians. Not only have the town council no right of intervention in this matter in their capacity as sanitary authority, but they are actually kept in the dark as to the state of their borough as regards vaccination, and they are without remedy in the matter.

GRAVES'S DISEASE WITH UNILATERAL SIGNS.

IN a recent number of *Gräfe's Archiv für Ophthalmologie* Dr. Percy Fridenburg of New York has described an interesting case of this nature. His paper is abstracted in a recent number of the *Neurologisches Centralblatt*. The patient was a woman aged twenty-four, a member of a nervous family, whose excitability and nervousness were increased by family misfortunes, and who complained of unusual weariness, palpitation, difficulty in breathing, frequent blushing, profuse perspiration, and weakness. The palpebral aperture on the left side was distinctly widened, so that in looking straight forward the sclerotic was visible two millimetres above the border of the cornea. The globe was distinct but not very prominent, Gräfe's sign was present, and vision was normal. The face, especially on the left side, was distinctly red, and with the slightest excitement this became extremely marked. Other symptoms were as follows: Swelling of the isthmus and the right lobe of the thyroid gland, fine fibrillary tremor of the tongue and hand, strong, occasionally intermittent cardiac impulse, accentuated second sound in the pulmonary area, diffuse impulse, increased cardiac dulness to the left, and a loud bruit over the jugular vein. There was no sign of valvular defect, and the pulse was 120. Respiration was superficial. Considerable improvement took place under the influence of rest, strophanthus, and bromide. The case is an interesting example of Graves's disease in which the exophthalmos was one-sided, and the writer has collected out of the literature of the subject as many as thirteen similar cases.

A PLAGUE OF ACARI.

ONE of the weirdest conceptions of the talented writer of "The Time Machine" is the monstrously overgrown centipede putting to flight the degenerate human beings as it comes looping along with armour-plates rattling, its gigantic head towering higher than the tallest elephant. After myriads of years the indomitable insect race, breaking through the fixed limitations of the old dispensation, has at length been rewarded by corporeal growth commensurate with its courage and perseverance, while, on the other hand, pleasure-loving and pain-fearing mortals have degenerated into loathsome pigmies. It is fortunate for the inhabitants of Barfleur that Mr. Wells's blood-curdling vision is referable to the remotest future and that the barrier restraining the potentiality of the insect world not only still remains impassable, but is also likely to continue so for some considerable time to come. With marvellous suddenness an entire quarter of the ancient seaport was recently invaded by a veritable horde of acari, huge in respect of number if not individually, and plenteously endowed with the energetic, not to say aggressive, qualities so greatly belauded by the ingenious Mr. Wells. With persistency worthy of a better cause the minute raiders commenced operations by entrenching themselves securely in furniture and hangings and then sallied forth on marauding expeditions until kitchens, storerooms, and wardrobes were all occupied by outlying parties. Next they attacked the food and clothing, and finally they captured the bodies of the hapless Barfleurians themselves, establishing well-nigh ineradicable depôts wherever the presence of hair afforded them facilities. In one particular alone could it be said that the intrusive mites were deserving of commendation. Contrary to the customs prevailing among certain of their congeners they refrained from burrowing beneath the epidermis of their unwilling hosts, who consequently, as the account now before us has it, remained free from cutaneous lesions. Had the very vigorous invaders taken to sinking tunnels after the fashion of their allies, the Sarcoptes scabiei, the condition of the Barfleurians would have been truly appalling, for even as it was the irritation, mental as well as corporeal, due to their ubiquitous tormentors became so unbearable that the prefect had to be invoked on the principle of the *deus ex machinâ*. Barfleur, however, boasts of a Conseil d'Hygiène, and very naturally the provincial ruler referred the matter to that learned body for investigation and report. The contaminated houses were accordingly noted and disinfected, but the results were negative. Nothing was capable of dislodging the pertinacious and impertinent creatures, which actually seemed to thrive on the means adopted for their repression. At length, tired of the contest, the local authorities appealed to the Natural History Museum of Paris, begging for advice as to the best way of obtaining deliverance from this incubus. In the opinion of the museum *savants* the intruders were closely allied to the acari which are to be met with in places where organic matter is slowly undergoing the process of dry putrefaction—as, for example, in herbaria or on anatomical preparations, stuffed birds, mummies, preserves, dried and candied fruits, &c.—but inasmuch as the precise species could not be determined at a distance an expert would be designated to hold an investigation on the spot. M. Perrier having been selected for the duty consequently proceeded to Barfleur, and after some time succeeded in completely unmasking the enemy. The acarus by which Barfleur has been so seriously disturbed turns out to be the Glyciphagus domesticus, a variety hitherto regarded as extremely rare; but although it might have been thought soothing to the feelings of the victims to learn that their visitors were such distinguished members of the Arachnidæ, they were nevertheless prosaic enough to maintain that the chief matter at issue was how to get rid of them. On this point, however, they were speedily reassured by the museum authorities, who drew attention to the fact, which apparently was outside the ken of the Conseil d'Hygiène, that the sulphur treatment systematically employed is almost infallible. Further interesting details will be found in our Paris correspondent's letter in THE LANCET of May 9th.

PREVENTION OF CRUELTY TO CHILDREN.

THAT admirable body "The National Society for the Prevention of Cruelty to Children" held its annual public meeting upon May 12th at the Mansion House, and we are glad to see that the society is flourishing, although the mere fact of its existence discloses a most lamentable state of things. Sir Richard Webster in moving a resolution pointed out that although the society had an exceedingly difficult task to perform, and although naturally they occasionally made mistakes, yet in the cases which they brought before the courts 96 per cent. convictions were obtained. We have lately commented in these columns upon some specially gross cases of cruelty, and it is gratifying to think how much brutality has been stopped from going further, how many human fiends have been punished and, we hope, made to pause and consider before beginning systematic torture by the operation of this society. We are glad to see that funds are plentiful and that the society has become national, with

Digitized by Google

a Royal charter, instead of metropolitan. Its objects appeal to every class, a distinction which it shares with perhaps only one other society, the National Lifeboat Institution. In nearly every other organisation the faddist can find something to cavil at. In most the religious apple of discord comes in, and even in such a matter as strengthening of the navy some well meaning fanatics see harm. But the bringing about the comfort and happiness of a helpless child is a matter which must appeal to everyone. Not that we object to corporal punishment for unruly children, be they the offspring of a duke or a dustman, holding with the remark of a great authority—"Cocker thy child and he shall make thee afraid, but beat him on the sides when he is young lest he wax stubborn and regard thee not." But wholesome discipline is a very different thing from cruelty.

PURCHASE OF THE SMALL-POX HOSPITAL BY THE ISLINGTON GUARDIANS.

THE guardians of Islington have agreed with the trustees of the Small-pox Hospital of Highgate to purchase the hospital with the nine acres of ground in which it stands on the hill for the sum of £52,000. We intimated some weeks ago that this seemed to be the best way for the guardians out of a muddle into which they had been brought by various circumstances and qualities which we need not describe, but which was seriously affecting their reputation as men of business and the interests of the huge number of poor committed to their charge. It is only fair to say that a leading member, who had charged himself with the responsibility of a most inadequate, temporary, and costly scheme, at once abandoned it in favour of purchase of the hospital, and so hastened the termination of a discussion which has lasted for years and has seriously compromised the reputation of the board as regards fitness for the enormous administrative duties which it has to discharge. We can only hope that with this purchase a new spirit of usefulness will prevail and that in the management of the sick poor of the largest parish in the United Kingdom an example of generous economy will be set which will command an extensive following.

VITALITY OF THE DIPHTHERITIC BACILLUS OUT OF THE BODY.

FLÜGGE in his *Grundriss der Hygiene*, published in 1889, stated that the microbes of diphtheria retained their virulence for ten days in the form of dust and from four to six weeks if dried in dense layers; but in a paper on the means by which the disease is spread, which appeared in the *Archiv für Hygiene* in 1894,[1] he expresses his incredulity as to aerial diffusion of diphtheria beyond the range of personal intercourse on the ground that the degree of desiccation required for the floating and conveyance of the bacilli in currents of air would be fatal to them. Roux and Yersin and Pernice and Scagliosi had carried out some experiments with portions of the membrane, but Carlo Reyes, deeming these unsatisfactory, since it was not by such means but rather by the saliva, mucous discharges, and similar fluids that the infection took place, undertook an inquiry into the subject, using pieces of linen or cotton, silk, paper, sand, and finely pulverised and sifted earth, which he saturated with emulsions in water of pure cultures of great virulence. These materials were allowed to dry spontaneously and were then exposed to light or were kept in darkness in air of the normal humidity at ordinary temperatures, or maintained in a state of saturation; and in atmospheres artificially dried by H_2SO_4 or kept at a constant temperature of 37° C. His results, which appear in the *Annali d'Igiene Sperimentale*,[2] show that in chemically and absolutely dried air Löffler's bacilli died in all cases within a few hours, forty-eight at the most; that light had, as a rule, but little influence; that under other conditions they retained their vitality on silk and paper for a few days only in dry, and for about a week in moist, air; on cotton or linen for from five to eighteen days, longer when moist than when dry; in sand, exposed to light and with a dry atmosphere for five days only, but, in darkness, for sixteen or eighteen days, and as long again with a moist atmosphere; while in fine earth they retained their vitality for from 75 to 105 days in dry air and were still active in damp air after 120 days. He also exposed vessels of water at different heights above the floor to dry dust containing living microbes raised by draughts produced by mechanical means, with the result that cultures were successfully obtained from most, thus demonstrating not only the possibility of the aerial diffusion of the virus for various periods, but its persistence in moist earth for an almost indefinite time. Though, as a rule, he observed a progressive attenuation of the virus, the fact that in moist earth, which had previously been desiccated so as to permit of its reduction to an impalpable powder, the microbes were still living after the lapse of 120 days suggests the possibility of their permanent existence and reproduction in soil charged with pabulum in the form of decomposing organic matter; in other words, that diphtheria may be one of those filth diseases in the life-history of whose microbes their parasiticism is an accidental stage.

"THE PLAINS OF AUSTRALIA."

THE place occupied by Australia as a health resort makes Mr. Boxall's article on "The Plains of Australia" in the *Contemporary Review* interesting to medical readers. "The mammals of Australia," says the writer, "represent the early tertiary or kainozoic age, and it may be reasonably assumed that the land in which they dwell afforded, in its original condition, before it was brought under the influence of the white man, an excellent opportunity for estimating what the condition of the earth was in other continents during the marsupial era or before the evolution of the great ruminant families." In the early days of Australian colonisation the land in the plains of the interior was regarded as "rotten," and the opinion was generally held that it would never be fit for occupation. But on these vast plains a hundred million of sheep are now pastured besides large numbers of cattle and horses. There is a consensus of opinion that when the early explorers penetrated to these plains they found them barren and inhospitable, almost utterly waterless, practically without inhabitant, and the soil so soft and insecure that horses and carts sank deeply into it. But these plains—or at least those portions of them which lie on the edge of the settled districts—are now talked of as the future granary of Australia when the proposed irrigation schemes are completed, and the change, in Mr. Boxall's view, is simply due to the trampling of innumerable sheep and cattle. It is believed that a range of mountains once stretched across the Australian continent from east to west, and that it has disappeared by denudation, the material of which it was composed having been slowly carried away by flood waters and deposited as sediment over vast areas. "In other lands where similar deposits were formed they were trampled down and consolidated, stratum by stratum, by herds of elephants, camels, llama, buffalo, bison, oxen, sheep, deer, and other highly gregarious animals. In Australia the kangaroo was incapable of performing a similar work. The kangaroo is not gregarious to

[2] Vol. v., 1895.

Digitized by Google

the same extent as the sheep or deer. Out on the plains only four or five are seen together even now. Before the advent of the white man with his flocks and herds the kangaroo only ranged in the neighbourhood of permanent water where the land was firm enough to support him. No doubt, when he was driven out on the rotten ground by dog or man, the great bird-like claw on his hind leg afforded a better support than the hoof of the sheep or bullock. The great strength capable of being exerted in the hind leg of the kangaroo would also enable him to extricate himself from a bog more easily than animals of a higher type of development. His short forepaws would be useful in 'clawing' himself along over rotten ground. But kangaroos do not follow each other and make tracks, and this is how the sedimentary deposits of the Ganges, the Nile, the Amazon, the Mississippi, and other deltas have been principally consolidated and compacted." The "rottenness" of the soil of the Australian plains in the early days of colonisation is shown by such facts as that a walking-stick could be thrust its full length into what looked like solid earth without using any special effort, a horse or bullock sunk up to his belly in the soil, and a full-woolled sheep could not extricate itself but had to be rescued. While this condition of things lasted the land was not flooded, as the waters sank into the porous earth and left their sediment resting lightly on the top. It is believed that these waters escape somewhere to the ocean, and in the Mount Gambier district water has been found running in underground channels at the rate of four or five miles an hour. Irrigation is alone required to make the Australian plains productive. "The plains of Australia," concludes Mr. Boxall, "are singularly alike, and if the plains of Northern and Western Australia can be consolidated by the trampling of stock, as I believe those of the eastern districts have been, the time is not far distant when the word 'desert' may be wiped off the map of Australia, and the true character of its vast plains become more generally understood and appreciated."

"PSEUDO-ACTINOMYCOSIS."

IN the *Russian Archives of Pathology, Clinical Medicine, and Bacteriology* Dr. T. G. Savchenko relates an interesting case of what, clinically speaking, was actinomycosis, but which differed from ordinary forms of this affection in its pathological course. Dr. Savchenko has seen several cases in Kieff and all except this one were due to fungi as ordinarily described. The patient was a peasant thirty years of age who had passed through his period of military service and had afterwards worked in the fields, being, in fact, in robust health until his illness began, which was about May, 1893, when he began to feel pain in his back. Subsequently a tumour appeared on the left side of the chest, which ultimately burst the skin and discharged large quantities of pus. When admitted into the St. Cyril Hospital, Kieff, in September, 1893, the tumour—which extended from the sternum to the left axilla and from the clavicle to the fifth intercostal space—was firm and covered by bluish-red skin. There were four sinuses with everted discoloured edges, from which pus with a peculiar disagreeable smell was discharged, together with a large number of whitish granules. There was but little cough and no sputum. The lungs gave no indication of disease and the urine was free from albumin and casts. New abscesses continued to form in the part affected and more than one operation was performed, but by April, 1895, the patient was discharged practically cured. The unpleasant-smelling pus was present throughout the whole course of the disease. It was significant, too, that the granulations occupying the sinuses were of a brown colour, very easily broken down, and contained a large quantity of blood. The chief interest of the case lies in the microscopic and bacteriological examination. When examined with low powers the granules did not look unlike those of actinomycosis, but when high powers were used it was seen that they were totally distinct, being, in fact, zooglœa made up of numbers of bacteria differing from one another in size. Bacilli were also contained in the pus apart from the granules, some being free and others within leucocytes. The bacteria were all stained by aniline colours, but not by the Gram stain. When isolated they were found to be absolutely anaerobic and never formed colonies on the surface of nutrient media. In glycerin jelly isolated granules were formed consisting of bacilli. A rabbit inoculated with a pure culture always presented an abscess in which the same bacilli, sometimes massed in zooglœa, were found, and always had the specific smell which was noticed in the patient and which was always present in the cultures. Dr. Savchenko proposes for this affection the term "bacillary pseudo-actinomycosis."

IMPROVEMENTS IN THE NEW PHOTOGRAPHY.

WE mentioned three weeks ago some experiments which we made with some sensitised metal plates submitted to us by Mr. Strauss Collin of Bush-lane House, Cannon-street, E.C. We have since obtained excellent results with these in THE LANCET Laboratory. They are developed in the ordinary way, using "rodinal" preferably as a developer, and fixed in the hyposulphite bath. Very thorough washing is the next step. The image which first appears on developing vanishes in the hyposulphite solution. When the plate, after washing, is, however, placed in a solution of perchloride of mercury the image reappears with great distinctness and with excellent detail. For medical work the employment of these plates offers undoubted advantages. Thus the thin sheeting upon which the sensitised film is spread may be adapted to any shape, and, unlike glass plates, is not easily fractured, so that it may be placed under the body of a patient without risk of breaking. Moreover, as will be gathered from the foregoing description of the process of development, a positive not unlike a ferrotype is at once obtained. The "tones" are good and the plates fairly rapid, the exposure we adopted in the case of the ankle being three minutes.

EXCITABILITY OF NERVES AFTER SECTION.

IN the *Archives de Physiologie* a paper by Arloing recently appeared in which were detailed a number of important experiments in reference to the duration of the excitability of the peripheral end of a cut nerve in warm-blooded animals. An abstract of this paper was published in the last number of the *Neurologisches Centralblatt*. Waller and Ranvier showed long ago that in pigeons and rodents excitability rapidly disappeared—in the course of two or three days. Arloing has investigated this variation very carefully, and according to his experiments the excitability of the peripheral end of the cut facial nerves in ungulates disappears in from eight to ten days. Microscopical examination of the nerve at this period shows disintegration of the myelin into drops in places, while at other parts the myelin is intact or shows only some irregularity of its borders. The individual differences are very striking. Thus in one case the peripheral end of the facial nerve was found excitable thirty days after section. In the same individual also the different nerves showed different conditions. Thus in a dog the facial nerve was excitable at its peripheral end five days after section, while at this time the median nerve was not excitable. As a rule the excitability of the cranial nerves took longer to disappear than that of the spinal nerves. In the same nerves also the different bundles lost their excitability at different periods. For

Digitized by Google

instance, in the vagus the inhibitory nerves of the heart died first, next the motor nerves for the œsophagus and larynx, while the accelerator fibres for the heart lost their excitability distinctly later, and last of all to die was a peculiar bundle, excitation of which brought about arrest of the heart in systole. This is the bundle which Arloing has already described as the "ordinary motor nerve of the heart muscle."

SIR JOHN MILLAIS.

IN view of the many unfounded rumours which are rife concerning the condition of Sir John Millais we think it right to state that the condition of affairs is as follows. On the night of Saturday, May 9th, urgent dyspnœa set in. This gradually increased, and early on Sunday morning Mr. Treves, assisted by Mr. G. H. Hames, considered it necessary to perform a tracheotomy. Sir John Millais was much relieved by the operation and has since gone on well. He sleeps well, and there are no chest complications. In addition to Mr. Treves and Mr. Hames, Sir Richard Quain is in attendance.

THE MEDICAL OFFICER OF THE ADMINISTRATIVE COUNTY OF LONDON.

THE average ratepayer is apt, and with good reason, to kick against the constantly increasing expenditure of the London County Council. But we fancy that the increase in the salary of the medical-officer, Mr. Shirley Murphy, from £1000 to £1250 will meet with nothing but approval. The medical and hygienic work of the London County Council is enormous, and the admirable way in which Mr. Shirley Murphy and his assistants direct it is well known. We are glad to see that an amendment to increase the salary to £1200 by an annual rise of £50 was negatived and the committee's original recommendation carried by 70 votes to 31.

PREVENTION OF HÆMORRHAGE IN DISARTICULATION AT THE HIP-JOINT.

AMPUTATION at the hip-joint has always been accompanied by a very high mortality, and two causes especially can be assigned to this great death-rate—namely, infection and shock. The deaths due to infection are now much less frequent than they were in the pre-antiseptic days, but shock still remains responsible for a very large proportion of deaths. A great part of this shock is caused by the large amount of blood which is so often lost at this operation, and many attempts have been made to diminish the hæmorrhage. One of the most recent methods was brought forward by Dr. V. Chalot, Professor of Clinical Surgery at the Faculty of Medicine of Toulouse, at the Huitième Congrès de Chirurgie, held at Lyons. He suggests that a slightly curved incision, four or five centimetres in length, should be made about two centimetres internal to the anterior superior iliac spine, and the anterior abdominal muscles then divided, so that the peritoneum can be gently raised from the iliac fossa. When this is done the common iliac artery can be felt on the inner border of the psoas muscle. An assistant places on the artery the tips of the middle and ring fingers of the left hand for the right side of the patient, and of the right hand for the left side, at the same time grasping the iliac crest with the forefinger and the thumb, while the little finger rests on the abdominal wall. The compression is made against the ala of the sacrum, and its efficacy is judged by the cessation of the femoral pulsation. The amputation is then proceeded with in the ordinary way. Dr. Chalot quoted a case in which he had employed this method with success, and with only a small amount of hæmorrhage.

THE HEALTH OF SIR J. RUSSELL REYNOLDS.

THE news which was announced at the beginning of the week of the serious illness of Sir J. Russell Reynolds came as a surprise to all but a few who were very well informed. His request that he should not be re-elected as President of the Royal College of Physicians of London might have been taken as a preparation for the bad tidings, for he was not the man to escape responsibilities that he had once accepted until it had become clear to him that to burden himself further with them would be wrong. But his indisposition was so ill defined and the absence of important indications of any organic mischief so entire that the serious symptoms which set in last Saturday night were as unexpected as alarming. But they were not without a definite cause. Sir J. Russell Reynolds had improved under rest, care, and change of air, but on April 23rd, after seeing some patients at home, he returned from a drive, and in alighting from his carriage slipped on his own doorstep. This accident, unfortunately, caused him to be confined to bed, and consequent on the shock and increasing weakness pulmonary complications supervened. We are very glad to be able to announce that a slight improvement, shown by the abatement of temperature and the diminished frequency of respiration, which took place on Monday has been maintained; and although the patient's condition is still one to cause the deepest anxiety, his medical advisers now allow us to hope that the rally is perhaps not temporary but the commencement of a return to strength. Dr. Barlow and Dr. Buzzard have seen Sir J. Russell Reynolds regularly with Mr. Cooper Bentham, who has been in constant and assiduous attention. Dr. Wilks and Dr. Gowers have also seen Sir J. Russell Reynolds in consultation.

THE annual general meeting of the Pathological Society of London for the election of officers and council, and other business, will be held at 20, Hanover-square on May 19th, at 8.30 P.M. Mr. Stanley Boyd will propose the following resolution: "That in the opinion of this meeting it is expedient that ladies, who are duly qualified medical practitioners, should be eligible for the membership of this society." The result of the voting on this motion will be awaited by the profession with no little interest and curiosity. By the way, why do not the ladies unite to form a medical society of their own? Some doubt seems to be felt as to whether the medical societies will follow the example set them by the British Medical Association.

MR. CHAMBERLAIN has been informed by telegram from the Governor of Hong-Kong that seventy-four fresh cases of bubonic plague occurred in the colony in the week ending May 12th, and that the number of deaths from the plague in the same period was sixty-four.

DR. GEORGE OLIVER will deliver the Croonian Lectures—A Contribution to the Study of the Blood and of the Circulation—at the Royal College of Physicians of London, Pall Mall East, on June 2nd, 4th, 9th, and 11th. The lectures will commence at 5 P.M.

DR. JOHN ANDERSON, C.I.E., M.D. St. And., F.R.C.P. Lond., Physician to the Seamen's *Dreadnought* Hospital, has been appointed Lecturer on Diseases of Tropical Climates at St. Mary's Hospital Medical School.

MR. A. PEARCE GOULD has been appointed Surgeon to the Middlesex Hospital.

THE annual dinner of old students of King's College,

Digitized by Google

London, will be held at the Holborn Restaurant on Monday, June 29th, Sir Benjamin Baker, K.C.M.G., LL.D., F.R.S., President of the Institution of Civil Engineers, in the chair.

Pharmacology and Therapeutics.
